In one series of experiments 19 vats of cream averaging 761 lbs. each were pasteurized at 140° F. With a steam pressure of 73.9 lbs. it required an average of 16.8 minutes to raise the temperature from 56.5 to 140°. In pasteurizing cream at 160° 20 vats were used, averaging 765 lbs. each. With a steam pressure of 72.3 lbs. it required an average of 22.2 minutes to raise the temperature from 56.8 to 160°. In a third series 19 vats of cream averaging 758 lbs. each were pasteurized at 180°. With a steam pressure of 74 lbs. it required an average of 34.4 minutes to raise the temperature from 57.6 to 180°.

The cream pasteurized at 140° was cooled to the churning temperature at an average rate of 2.9° per minute, that pasteurized at 160° was cooled 3.4° per minute, and that pasteurized at 180° was cooled 3.9° per minute. In the cooling experiments the water at the intake averaged about 50° in temperature.

The authors conclude that "in pasteurization of cream at different temperatures, namely, 140° for 25 minutes, 160° for 10 minutes, and 180°, with immediate cooling, the temperature of 160° for 10 minutes was the most effective in destroying total microorganisms. Pasteurization of cream at 160 or 180° proved more efficient in killing molds and nonacid-forming organisms than pasteurization at 140°.

"The only noticeable change in composition of cream due to pasteurization was a slight decrease in percentage of water, and a consequent increase in percentage of total solids. There was a slight decrease in acidity of the cream after pasteurization at temperatures of 140 and 160°. Cream pasteurized at 180° showed on the average less decrease in percentage of acid. . . . The numerous microscopical examinations of fat globules in raw and pasteurized cream show that at the higher temperatures (160 and 180°) the fat globules tend to coalesce or unite. . . .

"In no instance was it noticed that the high pasteurization temperatures unfavorably affected the body of the butter. Butter made from cream pasteurized at 180° retained its keeping qualities the best. The different temperatures of pasteurization did not have any important effect on the chemical composition of the butter."

#### VETERINARY MEDICINE.

Eighth biennial report of the State veterinarian of California for the two years ending June 30, 1916, C. Keane (Bien. Rpt. State Vet. Cal., 8 (1915–16), pp. 24).—This report, dealing with the occurrence of and work with the more important contagious diseases of live stock in California, includes papers on Hemorrhagic Septicemia, by J. P. Iverson (pp. 8–10), and Studies to Diagnose a Fatal Disease of Cattle in the Mountainous Regions of California, by K. F. Meyer (pp. 10–17).

Report of the bureau of veterinary science, C. F. Dawson et al. (Ann. Rpt. Bd. Health Fla., 28 (1916), pp. 216-247, figs. 2).—This report of the work of the year, dealing especially with tick eradication, includes directions for the preparation of dips and the dipping of cattle, together with plans for the construction of a dipping vat. Some diseases hitherto not known to exist in Florida are also briefly considered, among which are a tapeworm (Tænia marginata) in the liver of swine, enzootic pneumonia in young pigs, takosis in goats, stomach roundworm in sheep, and demodectic mange in swine.

Fifth annual report of the commissioner of animal industry for the year ended November 30, 1916, L. H. Howard (Ann. Rpt. Comr. Anim. Indus. [Mass.], 5 (1916), pp. 53).—Reports are given on the occurrence of and control work with the more important infectious diseases of animals, particularly tuberculosis and hog cholera.

Live-stock sanitation, H. T. Graves ([Bien.] Rpt. Dept. Agr. Wash., 2 (1915-16), pp. 63-89).—This report deals with the occurrence of and work with contagious diseases of animals in Washington State, including bovine tuberculosis, foot-and-mouth disease, glanders, hog cholera, etc. A discussion of the pure-bred accredited herd plan as related to tuberculosis is included.

Proceedings of the Wisconsin Veterinary Medical Association (Proc. Wis. Vet. Med. Assoc., 2 (1917), pp. 176, figs. 4).—The proceedings of the second annual meeting, held at Madison in January, 1917, are reported in full.

Biennial report of the State veterinarian of the State of Wyoming for the years 1913 and 1914 ending September 30, 1914, B. F. Davis (Bien. Rpt. State Vet. Wyo., 1913-14, pp. 120).—In reporting upon the work with diseases of live stock particular attention is given to tuberculosis and dourine eradication.

Biennial report of the State veterinarian, State of Wyoming, for the period September 30, 1914, to September 30, 1916, A. W. FRENCH (Bien. Rpt. State Vet. Wyo., 1915-16, pp. 90, figs. 6).—A report similar to the above.

**Progress** in veterinary work [in India] (*Rpt. Prog. Agr. India, 1915-16*, *pp. 95-100*).—A progress report on veterinary work for the year ended June 30, 1916.

Chlor-antiseptics, H. S. Eakins (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 2, pp. 221-229).—Formulas for the preparation of Dakin's solution and its various modifications are submitted and discussed.

The treatment of wounds with the polyvalent serum of Leclainche and Vallée, A. Guillaume and G. Bittner (Rev. Gén. Med. Vét., 26 (1917), No. 302-303, pp. 67-79).—Observations of a number of cases of wound treatment in horses injured on the field with a polyvalent serum are noted in detail. The use of the serum has yielded excellent results and is considered to be an important adjuvant in wound therapy.

Mechanism of the serum reactions, H. R. Dean (Lancet [London], 1917, I, No. 2, pp. 45-50, figs. 4).—This is a general review of the work on the subject, in which the author concludes that in all the serum reactions (precipitation, complement fixation, and agglutination) the immediate result is an aggre-

gation of the globulin particles around the antigen. "The degree to which the aggregation or precipitation proceeds depends entirely on the experimental conditions, on the relative proportions of antigen and antibody in the mixture, on the nature of the antigen-containing substance, red corpuscle, bacillus, or normal serum, on the presence of some third factor, a normal serum containing complement or conglutinin."

The various serum reactions are thus considered to be the observation and measurement of a single reaction. It is indicated that the main phenomena of the reaction are most readily accounted for by the adsorption rather than by the side-chain theory.

The influence of serum upon the staining of bacteria in suspensions, M. S. FLEISHER (Jour. Med. Research, 36 (1917), No. 1, pp. 31-49).—Serum added to a mixture of bacteria and certain dilute basic stains (neutral red, methylene blue, gentian violet, methyl green, and Bismark brown), 1 part in 25, prevented the staining of the organisms. A similar although weaker action was produced by using egg albumin in the place of serum, and a very weak action was exerted by 3 per cent gelatin solutions.

The addition of acids or alkalis did not interfere with the inhibitory action of the other substances. The action of the serum diminished with its diminishing concentration, and an increasing concentration of the stain tended to overcome the inhibitory action of the serum. Heating the serum or the bacteria did not interfere with the inhibition of the staining.

It is deemed probable that this inhibitory phenomenon of the serum is due to a protective colloid action.

On the cause of negative tissue transplantation.—III, The cleavage of tissue protein of one animal species by the blood serum of an animal of another species, A. Albanese (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), II, No. 12, pp. 501-505).—Tabulated data of the action of the blood serum of the rat on the protein of the mouse, rabbit, guinea pig. and dog; of the blood serum of the mouse on the protein of the rat; of the blood serum of the guinea pig on the protein of the rat, mouse, dog, and rabbit; and of the blood serum of the rabbit on the protein of the rat, mouse, and guinea pig are submitted. The Abderhalden procedure was used in the study. The results are briefly discussed.

The origin of the proteolytic ferments of the blood.—The question of the specific character of certain ferments, L. H. SLOAN (Amer. Jour. Physiol., 39 (1915), No. 1, pp. 9-19).—Data relative to the action of blood serum from pregnant individuals on human placenta and on various tissues (pancreas, liver, and kidney) and of blood serum from normal individuals and blood serum from various pathological conditions on human placenta are reported.

From the results it is concluded that there is an increased proteolytic ferment action of the blood serum during pregnancy. This increased activity is considered probably due to an increase in the polyvalent ferments. Normal blood serum was found to have a weak nonspecific proteolytic action. Since many advanced pathological conditions gave a positive reaction, it is indicated that the Abderhalden method does not "provide a reliable test for the differential diagnosis between the strictly physiological state of pregnancy and certain pathological conditions." The test is considered to be quantitative and not qualitative.

The origin of the proteolytic ferments.—II, Concerning the character of certain ferments, L. H. Sloan (Amer. Jour. Physiol., 42 (1917), No. 4, pp. 558-571).—The author has studied in detail the action of blood serum of normal and pregnant dogs on human placenta, the action of blood serum of dogs injected

with placental suspension, the action of serum of dogs injected with split products of pepsin-trypsin digestion of human placenta, the action of serum of pregnant dogs injected with placental suspension, and the effect of feeding on the amino-acid content and the ferment strength of the blood serum, using placenta as substrate.

It is concluded that normal blood serum contains a weak proteolytic ferment which carries digestion to the amino-acid stage. The concentration of this ferment is not constant. "There is an increased proteolytic ferment action of serum during pregnancy as shown by the dialysis method of Abderhalden. This can not be detected by the Van Slyke method [E. S. R., 34, p. 577]. The injection of placental suspension does not give rise to an increased production or mobilization of ferments when tested by the dialysis method or the Van Slyke method. The injection of the split products of pepsin-trypsin digestion of human placenta gives rise to an increase in the ferments. This increase can be shown by the dialysis method but not by means of the Van Slyke method. The theory underlying the Abderhalden reaction as advanced by Abderhalden does not explain the increase in ferments found during pregnancy. The basis of the theory would seem to be the entrance of split products of placental hydrolysis rather than of chorionic villi and cells. The Van Slyke method is not applicable to determinations of the above character in which a nonsoluble, moist, complex, protein substance is incubated with serum in a test tube but without dialysis."

Desiccated anthrax antigen for immunization purposes, N. S. Ferry (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 2, pp. 200-203).—The preparation of a desiccated spore vaccine in a manner similar to the preparation of spore vaccine in suspension (E. S. R., 34, p. 579) is noted. The growth was scraped from the agar and incorporated with a sterile diluent and dried at room temperature.

No deterioration in the virulence of a preparation one year old and kept at room temperature was observed. It is indicated that the most satisfactory method of using the vaccine would be in the form of properly standardized pellets.

Special report of the State veterinarian on foot-and-mouth disease in Virginia, its cause, how spread among cattle, other ruminants, and swine, and its control and eradication, J. G. FERNEYHOUGH (Richmond, Va.: State, 1916, pp. 38, pls. 4).—This reports upon control and eradication work by the Virginia State Live Stock Sanitary Board during the outbreak of foot-and-mouth disease which occurred in the fall of 1914.

Johne's disease.—The reactions of animals to "Johnin," J. McFadyean, A. L. Sheather, and J. T. Edwards (Jour. Compar. Path. and Ther., 29 (1916), Nos. 2, pp. 134-171; 3, pp. 201-243, figs. 25).—The substance "Johnin," used in the experiments reported, is analogous to tuberculin. The material was prepared from a strain of Johne's bacillus isolated from the intestine of a typical case of the disease, and the absence of tubercle bacilli from the strain was proved by animal experimentation. The strain, which had been cultivated for a number of years, would not grow on liquid or solid media unless extracts of some other acid-fast bacilli were present.

The first Johnin used was prepared from a surface growth on broth to which 4 per cent of an extract of human tubercle bacilli in 20 per cent glycerin had been added. The culture in the flask was heated for one hour and the organisms removed by passing the liquid through a Berkefeld filter. The clear filtrate thus obtained was used in some of the tests.

A preparation was also made by separating the bacilli from the liquid culture media by sedimentation, suspending in sterile distilled water, and then

removing by centrifugalization. A second washing was carried out, and the bacilli remaining were extracted by heating for one hour with 5 per cent glycerin in distilled water, then removed by centrifugalization or passing the liquid through a Berkefeld filter.

These preparations were approximately of the same strength, 10 cc. of the liquid representing the extract from 1 gm. of the wet bacilli. A concentrated Johnin used in the conjunctival and intracutaneous tests was prepared by evaporating the ordinary Johnin to one-fifth of its original volume or by extracting washed bacilli with 5 per cent glycerin in water in the proportion of 2 cc. to 1 gm, of the wet bacilli.

Subcutaneous, intracutaneous, and conjunctival tests of animals experimentally infected with the disease and animals experimentally infected with numan, avian, and bovine tubercle bacilli are reported in detail. The Johnin produced distinct temperature reactions in animals affected with Johne's disease. Positive results were obtained by the intracutaneous procedure, but the application of the Johnin to the conjunctiva appeared to be incapable of producing distinct reactions. Reactions with the Johnin were also obtained in young animals infected with human, avian, or bovine tubercle bacilli.

A new Italian method for antirabic treatment, C. Fermi (Ann. 1g. Sper., n. ser., 26 (1916), Sup., pp. 164).—This volume describes the results of an experimental investigation. Part 1 consists of a description of the new method and its evolution; part 2 gives a comparison of the efficacy of the new method with other methods of antirabic treatment; and part 3 shows the duration of the immunizing power of the vaccine and serum vaccine and of the immunizing and neutralizing power of the new antirabic serum.

In the procedure a vaccine consisting of a 5 per cent emulsion of the virus, an antirabic serum obtained from the horse, and a serum vaccine consisting of one part of the antiserum and two of the vaccine, together with 1 per cent phenol, are used. The method of treatment and detailed tabulated data are described and discussed.

Binderpest.—Preparation of antiserum, A. W. SHILSTON (Agr. Research Inst. Pusa Bul. 64 (1916), pp. 18).—Experiments to determine the potency of sera taken 8, 12, and 16 days after the injection of virus, and to compare the results with those given by sera taken 15 and 17 days after injection, are reported.

The results indicate that the immune bodies are present in full amount in the serum 8 days after the injection of the virulent blood and citrate solution mixture. "By taking three bleedings at the rate of 6 cc. per pound body weight on the eighth, twelfth, and sixteenth days after injection a mixed serum was obtained of equal (hill bulls) or increased (buffaloes) potency to that obtained by taking two bleedings 15 and 17 days after injection at the rate of 6 cc. and 8 cc. per pound body weight, respectively. . . . The actual yield of serum after each injection was increased from 6.79 cc. per pound body weight by the two bleedings system to 9.6 cc. by the three bleedings system or an additional 2.81 cc. of serum per pound body weight; an increase of 41.4 per cent on the former output."

The saving of cost in the production of a large amount of serum by the new procedure is noted.

The piroplasmoses and means for their prevention and control, G. ALES-BANDEINI (Ann. Ig. [Rome], 27 (1917), No. 2, pp. 100-110; abs. in Rev. Appl. Ent., Ser. B, 5 (1917), No. 5, p. 71).—A brief review of the present status of the knowledge of piroplasmoses and babesiases and their control, including an account of the ticks implicated in their transmission.

The pathogenic action of Ixodidæ, S. E. PARODI (An. Soc. Rural Argentina, 51 (1917), No. 2, pp. 111-125, figs. 4).—An account of the protozoan parasites transmitted by ticks in Argentina and their effect upon the host.

Application of the complement-fixation test to tuberculosis, N. B. Burns, F. H. Slack, P. Castleman, and K. Bailey (Jour. Amer. Med. Assoc., 68 (1917), No. 19, pp. 1386-1389).—From the results of the investigation reported the authors indicate that the complement-fixation test appears specific for tuberculosis.

It is considered that the test will prove of great value as a diagnostic aid in cases showing suggestive physical signs, but in which it is impossible to demonstrate the presence of tubercle bacilli in the sputum. "In such cases positive complement-fixation reactions would be strong evidence of the disease. A single negative would be inconclusive, but several negatives would indicate that no active tuberculous process was present."

The value of determining whether a case of tuberculosis clinically apparently arrested still has an active focus, as indicated by positive reaction, is noted.

Complement fixation in tuberculosis with the "partial antigens" of Deyke and Much, A. C. Woods, G. E. Bushnell, and C. Maddux (Jour. Immunol., 2 (1917), No. 3, pp. 301-325).—One hundred and seventy-six normal and tuberculous sera were tested against partial antigens and against whole bacillus emulsion antigen. Ninety-one per cent of the sera from cases classed clinically as inactive tuberculosis reacted negatively to the antigens. Ninety per cent of the sera classed clinically as incipient tuberculosis, 87 per cent of those classed as active, and 92 per cent of those from advanced cases reacted positively to the partial antigens.

The results are discussed in some detail. A list of 26 references to the literature cited is included.

The influence of certain organic substances on the growth of the tubercle bacillus, P. A. Lewis (Jour. Expt. Med., 25 (1917), No. 3, pp. 441-459).—The growth-restraining power of a large number of anilin dyes on Bacillus tuberculosis and B. typhosus has been determined.

Many dyes were found to possess a special restraining power for the tubercle bacillus. "This capacity to restrain growth in the case of the tubercle bacillus apparently bears no simple relation to true disinfectant action. Opinion as to whether the active substances exert a truly specific activity against the tubercle bacillus or whether the activity is determined by the peculiar conditions imposed by the growth of this bacterium as a surface membrane is left for future consideration."

The influence of typhoid vaccine on tuberculous guinea pigs, Helen Baldwin and Elise S. L'Esperance (Jour. Immunol., 2 (1917), No. 3, pp. 283-299, pl. 1, figs. 11).—Experiments are reported which show that a greater resistance to tubercle inoculation developed in animals immunized against typhoid than in the unimmunized animals, and that animals with active tuberculosis appeared to possess an increased resistance when given typhoid vaccine.

The presence of the tubercle bacillus in butter, A. C. MARCHISOTTI (Rev. Facult. Agron. y Vet. La Plata, 2. ser., 12 (1917), No. 3, pp. 279-298).—In a bacteriological study of 25 samples of commercial butters the author found that 24 per cent contained tubercle bacilli. Fifty-two and nine-tenths per cent of the samples contained acid-fast organisms, the greater number of these, however, being pseudo-acid-resistant. The hygienic aspects of the results of the study are noted.

The procedures used and the detailed inoculation data are submitted.

Tuberculosis in the goat, Moussu (Compt. Rend. Acad. Agr. France, 3 (1917), No. 12, pp. 341-348).—A general discussion with special reference to

the hygienic importance of a proper diagnosis, especially where the milk is to be used. The difficulty often encountered in diagnosis is indicated.

Age determination of cattle in different countries (Abs. in Agr. News [Barbados], 16 (1917), No. 392, p. 133).—Attention is called to the fact that dentition formulas for the determination of age in cattle vary according to breed and environment.

Health herd book for breeders of pure-bred cattle and owners of high-grade dairy animals, V. A. Moore (Ithaca, N. Y.: Carpenter & Co., 1915, pp. [204], figs. 51).—This loose-leaf book contains blanks for recording the name of the animal, date of birth, date of purchase, price, etc.; identification markings; progeny; health, including record of tuberculin tests and statement and date of any sickness, abortion, udder trouble, or injuries; milk production; and pedigree.

In a prefatory note the author calls attention to the importance of a carefully kept record of the health of every animal of a herd, not only to the owner in the management of his herd but also to the prospective purchaser.

A rational and successful method of preventing abortion in cattle, A. T. Peters (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 2, pp. 211-214).—The author has obtained successful results in 106 herds through feeding a perfectly blended formula of mineral matter in sufficient quantity to replenish the lost mineral in the animal body. This was supplemented by a thorough disinfection of the stables and, where the cows showed indications of discharge, by injections of a saturated solution of bicarbonate of soda.

Abortion in dairy cattle, W. L. WILLIAMS (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 3, pp. 348-363, figs. 3).—A paper presented at the twentieth annual meeting of the U. S. Live Stock Sanitary Association, held at Chicago in December, 1916, which summarizes the present status of knowledge of the disease. See also a previous note (E. S. R., 34, p. 386).

A report upon an outbreak of stomatitis contagiosa, H. E. Gibbs (Vet. Jour., 73 (1917), No. 503, pp. 147-155, figs. 4).—A report of experiments conducted during a recent outbreak.

Investigation of a new variety of Nocardia bovis, Actinomyces lanfranchii, L. Sani (Ann. Ig. [Rome], 26 (1916), Nos. 9, pp. 570-580, figs. 5; 10, pp. 646-658).—Biological and morphological studies which have led to the identification of this new variety of the ray-fungus are reported.

Sheep poisoned by western goldenrod (Solidago spectabilis), S. Lockett (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 2, pp. 214-221).—The author reports upon losses among sheep in Nevada through feeding upon S. spectabilis, a plant which possesses definite nerve-poisoning properties, both in its natural green condition and when cured in hay.

"The symptoms produced may be acute (maniacal), subacute (producing slight cerebral stimulation and increased normal reflexes), or chronic (resulting finally in mental depression, ataxia, and palsy). These appear to depend upon the amount of the plant ingested in a given period of time. Five hundred gm. eaten in 8 hours produced within 23 hours a severe type of poisoning in a six to seven months lamb.

"Chloral hydrate in proper dosage would seem indicated as an antidote. The administration of 45 grains per rectum followed in 20 minutes by 90 grains per os was excessive in the case of the experimental lamb of six to seven months of age. This animal remained too long under the effect of the drug and the after stupor produced would in field practice militate against the chances of recovery under herd conditions."

The kidney worm of swine (Stephanurus dentatus), E. L. LUACES (Estac. Expt. Agron. Cuba Circ. 52 (1916), pp. 13, figs. 3).—A brief summary of infor-

mation relative to this parasite, the disease which it causes, and remedial measures.

"Piroplasmosis," "equine malaria," R. A. STOUTE (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 2, p. 239).—The author records the occurrence of this affection in Barbados in a 10-year-old mare imported from St. Croix.

Parasites of the dog in Michigan, M. C. Hall (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 3, pp. 383-396).—This is a summary of information based upon personal investigations and a review of the literature.

Trichina spiralis in the polar bear, H. Fox (Ann. Rpt. Zool. Soc. Phila., 45 (1917), p. 38).—The author records the discovery of encysted forms of trichina in almost unbelievable numbers, made at post-mortem examination of a polar bear which succumbed to disease at the Philadelphia Zoological Garden.

Mortality statistics of the fifth national egg-laying contest, Missouri, G. D. Horton (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 3 (1917), No. 9, pp. 70, 71).—It is concluded from the data here presented that at least 80 per cent of all sick or out-of-condition fowls, if treated in time, may be cured readily and at small cost.

A study of the fermenting properties of Bacterium pullorum and B. sanguinarium, S. A. Goldberg (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 2, pp. 203-210).—The author's investigations "show that the principal differences in the strains of B. pullorum and B. sanguinarium studied lie in the fact that B. pullorum produces gas in various carbohydrates while B. sanguinarium lacks this power in any of the carbohydrates used. This difference appears to be constant. Judging from the present classification of species of bacteria this difference in gas production as well as their different actions on milk, maltose, dulcite, dextrin, and isodulcite seem to indicate that these two organisms are two distinct species of bacteria."

Is Leucocytozoon anatis the cause of a new disease in ducks? A. B. Wickware (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 3 (1917), No. 9, pp. 67, 68).—Noted from another source (E. S. R., 36, p. 275).

# RURAL ENGINEERING.

Irrigation of rice in California, R. D. ROBERTSON (California Sta. Bul. 279 (1917), pp. 253-270, figs. 7).—This report, based on work done during 1913 to 1916 in cooperation with the Office of Public Roads and Rural Engineering and the Bureau of Plant Industry of the U. S. Department of Agriculture and the California State Department of Engineering and State Water Commission, describes the irrigation of rice in California, principally in the Sacramento Valley.

"Approximately 67,000 acres of rice were irrigated in California in 1916, the water supply being obtained principally from Sacramento and Feather Rivers. Only about 3,700 acres were irrigated by pumping from wells.

"Land is prepared for irrigation in contour checks, preparation consisting mainly in making ditches and levees and installing gates. The gates must be wide enough to admit the large heads of water used in the initial floodings. The irrigation season consists of two periods. Frequent light irrigations with relatively large heads of water are given to germinate the seed and to maintain growth until the plant is 4 to 6 in. high, and thereafter the land is continually submerged to a depth of 6 to 8 in, until the rice is matured.

"Measurements of the use of water in 1916 on 18 typical fields in Sacramento Valley showed a range of from 4.27 to 14.83 acre-feet per acre, an average depth applied of 8.23 ft., and an average of 47 acres served per cubic

foot per second. The heads of water used per acre averaged 0.052 cu. ft. per second before submergence and 0.034 during submergence. The lowest used was on fields with heavy retentive soil, where the preparation was good and the water carefully handled. The average annual use over a three-year period on a field near Biggs was 4.6 acre-feet per acre. During the three irrigation seasons the average precipitation was 0.23 ft. and evaporation 3.19 ft. Irrigation practice and requirements in California differ from those in the Gulf States, due mainly to different climatic conditions.

"Adequate drainage is essential to successful rice production. Planting and harvesting are both delayed while the soil remains wet and the removal of alkali salts and the relief of water-logged lands are dependent upon drainage facilities.

"The results of experiments made in 1914 to 1916, inclusive, on black clay adobe soil near Biggs indicated that 30 days after emergence of the plant is the best time for commencing submergence and that 6 in. is probably the most advantageous depth of submergence. Very poor yields were secured where no water was held on the land. Fluctuating the depth of water had very little effect on plant growth. More uniform temperatures of the water were found with the greater depths of submergence."

Annual irrigation revenue report of the Government of Bengal for the year 1915-16 (Ann. Irrig. Rev. Rpt. Bengal, 1915-16, pp. 73, pl. 1).—This reports administration work, expenditures, engineering projects, and revenues for the year 1915-16.

River discharge, J. C. Hoyt and N. C. Grover (New York: John Wiley & Sons, 1916, 4. ed. rev. and enl., pp. XII+210, pls. 11, figs. 39).—This is the fourth revised and enlarged edition of this book (E. S. R., 33, p. 287). Chapter 5, on Discussion and Use of Data, has been largely rewritten, and chapter 6, formerly entitled Conditions Affecting Stream Flow, has been expanded in scope to cover the field of hydrology as related to stream flow and the title changed accordingly.

Geology and water resources of Big Smoky, Clayton, and Alkali Spring Valleys, Nevada, O. E. Meinzer (U. S. Geol. Survey, Water-Supply Paper 423 (1917), pp. 167, pls. 15, figs. 11).—The first part of this report deals with the geology and water resources of a desert area of 1,300 square miles extending from the center of Nevada to within 20 miles of the California line.

"Several tens of thousands of acre-feet of ground water is probably contributed each year to the underground reservoirs of Big Smoky Valley. A part of this supply could be recovered for irrigation. Most of this water is in the upper valley, but a part is in the vicinity of Millers, in the lower valley. The water is in general of satisfactory quality for irrigation. Nearly all the poor water is in the southwestern part of the lower valley, where prospects for irrigation are practically lacking.

"A small part of the ground-water supply can be recovered by flowing wells, but full use of the supply is possible only by pumping. Throughout the extensive areas in which the depth to the water table does not exceed 10 ft. the soil contains injurious amounts of alkali. In the areas in which the depth to the water table ranges between 10 and 50 ft. there is enough good soil to utilize all the available ground water. These areas, however, also contain considerable gravelly, sandy, and alkaline soil.

"There are some prospects of obtaining flowing wells wherever the water table is near the surface, but the prospects are best on the west side of the upper valley. The flowing-well areas will be found to lie chiefly within the areas of alkali soil, but they may extend into adjacent areas of good soil. "Full utilization of the ground-water supply for irrigation will not be economically practicable until cheaper power or more valuable crops can be introduced than are now in sight. Developments that may be practicable at present are (1) the sinking of flowing wells of moderate depths in the restricted areas where fairly copious flows can be obtained and the soil is not irreclaimably alkaline; (2) the sinking of nonflowing wells and the installation of pumping plants for raising high-priced crops or for raising ordinary crops in localities where the conditions are exceptionally favorable or where the well water can be used to supplement surface-water supplies. . . . Existing conditions do not warrent the influx of a large number of settlers, nor of any without means to sink wells and make other necessary improvements."

The second part of this report deals with the geology and water resources of Clayton Valley, an area of about 570 square miles in Esmeralda County, Nev.

"Most of the soil of Clayton Valley is too gravelly, sandy, or alkaline for cultivation, but there is a small area, lying chiefly between the 50-ft. line and the salt-grass boundary, that can apparently be classed as agricultural soil. . . . The information available indicates that although water underlies Clayton Valley in considerable quantities, it can not be successfully utilized for irrigation because of its saline character and other unfavorable conditions."

The third part of the report deals with the geology and water resources of Alkali Spring Valley, an area of about 310 square miles lying almost entirely in Esmeralda County, Nev. "The wells that have been sunk in Alkali Spring Valley prove the existence of ground water in the valley fill. . . . If 5 per cent of the precipitation in the basin finds its way to the underground reservoir the annual contributions amount to about 5,000 acre-ft. . . .

"The valley fill of Alkali Spring Valley contains a supply of water that is of fairly good quality for domestic and boiler use and for irrigation. Although the quantity of water is not large, it is adequate for ordinary domestic, stock, and industrial purposes, and would probably be adequate for a small amount of irrigation. The valley contains considerable good soil, but the depth to the water table is too great to make pumping for irrigation profitable under present conditions except possibly for intensive market gardening."

Ground water in San Simon Valley, Arizona and New Mexico, A. T. Schwennesen (U. S. Geol. Survey, Water-Supply Paper 425-A (1917), pp. 35, pls. 3, figs. 2).—This report, prepared in cooperation with the Arizona Experiment Station, deals with the geology, physiography, water supply, and agriculture of an area 85 miles long and varying in width from 10 to 35 miles, which is located in southeastern Arizona and the adjacent part of New Mexico.

"Practically all the water in San Simon Valley is derived from the precipitation on the drainage basin; there is no considerable inflow of water from other basins. In the San Simon and Bowie areas there are two distinct ground-water horizons; an upper horizon in the younger stream deposits and a lower or artesian horizon in the deposits below the dense clay of the lake beds. In the San Simon area the ground water of the upper horizon is less than 100 ft. below the surface throughout a large tract extending along the axis of the valley. The supply has proved ample for watering stock, for domestic needs, and for the heavier demands of the railroad, and if it can be pumped economically it is probably large enough for considerable irrigation. It is doubtful whether it would be profitable at present to pump this supply for irrigation. In the Bowie region the supply at the upper ground-water horizon is very scanty and it is generally necessary to sink to the lower horizon, even for small supplies,

"In the lower ground-water horizon the water is under hydrostatic pressure, so that it rises in wells when the water-bearing beds are penetrated. In the San Simon flowing-well area the pressure is sufficient to cause this water to rise above the surface in wells. In the Bowie area the water is also under pressure and in some localities it rises close enough to the surface to be economically pumped for irrigation. Measurements show that the head and yield of wells has decreased considerably in the two-year period between 1913 and 1915. This increase is largely due to the filling of the uncased wells with sand and the caving of the walls of these wells, but it may in part be due to the increase in the number of wells and depletion of the artesian supply. It is of the utmost importance for the future welfare of the valley that all wells be properly cased to the bottom with heavy casing and be fitted with valves which will be closed when the water is not needed. . . .

"The flowing-well waters are mostly of the sodium carbonate type, but they generally contain only small amounts of dissolved solids and are of good quality for irrigation and domestic use. In the vicinity of Apache and Moore's Spur the ground-water supply is small and uncertain, but some water for stock and domestic purposes is obtained from shallow wells and springs. In the vicinity of Rodeo and in the central part of the valley north of Rodeo there is a considerable area in which the depth to the water table is less than 100 ft. In this area the supply is probably large, but on account of the lift that would be required it would probably not be profitable at present to pump it for irrigation. All the waters analyzed from the Rodeo area are good irrigating and domestic waters."

A section on general agriculture in the valley, by R. H. Forbes, is also included.

Report [of the California] State water problems conference (Sacramento, Cal.: State, 1916, pp. 125).—This report deals with the conservation and use of water, the flood problems of California, riparian rights, irrigation, underground water, reclamation, inland waterways, relation between navigation and irrigation, storage for flood control, interstate waters, water for mining, water for municipal purposes, expense and delay in water litigation and State aid in the interest of conservation.

Ditch flow found quickly and accurately with new portable weir, E. S. Fuller (Engin. News-Rec., 78 (1917), No. 7, pp. 373, 374, fig. 1).—A portable weir for use in quickly determining seepage losses along a canal is described and diagrammatically illustrated.

Determining daily discharge of canals affected by check control, H. W. Humphrey (*Reclam. Rec.* [U. S.], 8 (1917), No. 6, pp. 288-290, fig. 1).—The use of the Hall slope method in determining daily discharge of canals affected by variable slopes due to check control is demonstrated (E. S. R., 32, p. 382.).

The turbidity of water, A. A. Bado and R. A. Trelles (An. Soc. Quim. Argentina, 4 (1916), No. 16, pp. 283-293, figs. 4).—New methods and apparatus for determining turbidity in river waters, which are considered to be especially applicable to South American river waters, are described. All are based on the relative distances through which light or objects may be seen through the water.

Silt observations at Yuma gauging station, compiled by L. M. LAWSON (Reclam. Rec. [U. S.], 8 (1917), No. 5, pp. 240, 241, fig. 1).—Silt determinations begun in 1909 on the Colorado River are summarized.

"The maximum percentage of silt during the rising stage is carried at a discharge of approximately 26.000 second-feet, which is also the stage at which the river at this point reaches its maximum velocity—6.2 ft. per second.

During the falling stage of the river, the maximum percentage of silt is carried at a somewhat higher discharge. The maximum percentage of silt by weight observed is 4.16 per cent. The mean silt content and percentage by weight, 1909 to 1916, of the Colorado River at Yuma, without the Gila flow, is 0.7 per cent. At times of Gila discharge this percentage is 0.93. The weight of the wet deposited silt per cubic foot when dried is 86 lbs. The weight of 1 cu. ft. of solid dried silt is 159.3 lbs. The specific gravity of the silt is 2.6."

Sluicing silt to reduce canal leakage, F. J. Barnes (Engin. News-Rec., 78 (1917), No. 7, pp. 337-339, figs. 3).—This article summarizes operating experience on an experimental plant installed on the U. S. Reclamation Service Irrigation Project at Grand Valley, Colo.

Modern practice in wood-stave pipe design and suggestions for standard specifications, J. F. Partridge (*Proc. Amer. Soc. Civ. Engin.*, 43 (1917), No. 4, pp. 559-594).—"The object of this paper is to give engineers an idea of the difference between the various grades of wood pipes; to set forth a standard set of specifications for the assistance of engineers who have had no opportunity to become versed in their design; to safeguard those who contemplate building such pipe; and to remove doubt from the minds of those who view wood pipe as one of the vagaries of engineering practice and a medium to be resorted to only in temporary and cheap work."

The elements causing success or failure in wood stave pipe are enumerated as (1) kinds of wood used, (2) grade of lumber used, (3) method of curing lumber, (4) method of treating lumber, (5) location of pipe when built, (6) size and spacing of bands, and (7) methods used in erection, and quality of workmanship. These are discussed as applied to continuous-stave pipe and machine-banded pipe, and a plea is made for the adoption of uniform specifications, dividing each type into classes A, B, and C. The appendix contains the specifications for the two types and three classes of pipes, which are proposed as a basis for adoption by engineers.

The classification of continuous-stave pipe is as follows: "Class A—a pipe having a maximum life, under all conditions, and this will be 25 years when receiving no care whatsoever; a life greater than 25 years, if under continuous operation; and a probable life of 50 years, or more, if in continuous operation under at least a moderate head, if the bands are given attention and corroded ones are renewed. This includes pipe made from clear, air-dried redwood. Class B—this class includes coated pine or fir, in such a situation as to be open to continuous inspection, so that it may be given constant attention; comprising repainting staves and renewing bands. This pipe will be placed under class A, on theory only, as experience has not yet confirmed such an assumption. Class C—this class will have a maximum life of 10 years and an average life of 7 years. It will include uncoated fir, pine, or other suitable wood."

The classification of machine-banded pipe is as follows: "Class A—this class will have a life of from 15 to 25 years when receiving no attention; a longer life under ideal conditions, as when laid in soils having the least possible corrosive effect on the galvanized wire, and when operating under pressure, so as to insure complete saturation of the wood. Pipes of this class will be guaranteed to withstand severe conditions of overload, such as in hydroelectric work, general waterworks for city supply, and high-pressure pumping lines; and will be guaranteed to withstand an overload of 100 per cent under test. It will include pipes of clear, air-dried redwood, manufactured according to the specifications in the appendix. Class B—this class will have a life of at least 10 years, and a probable life not exceeding 15 years. It will include

pipe made of redwood, or of coated fir or pine, etc., manufactured according to present-day standards, as indicated by the specifications covering this class. Class C—pipes of this class will be used for temporary work only and may be manufactured from redwood, fir, pine, or any other wood, with or without coating, as desired."

Analyses of Fargo city water supply, R. Hulbert (North Dakota Sta. Spec. Bul., 4 (1917), No. 12, pp. 338-341).—Chemical and bacteriological analyses of samples of water from the Red River and of the same after undergoing purification at the Fargo city filtration plant showed that the purification process removed better than 99 per cent of the organisms present in the raw river water.

Investigations on the filtration of drinking water.—I, The theory of slow sand filtration, K. Kisskalt (Ztschr. Hyg. u. Infektionskrank., 80 (1915), No. 1, pp. 57-64. fig. 1).—Experiments are reported on the slow filtration of water through sand in which it was found that the addition of potassium cyanid killed the protozoa in the filter but did not injure the bacteria and thus destroyed the purifying action of the filter almost completely for some time. It is concluded, therefore, that the greatest part of the purification process of slow-sand filtration is due to the protozoa.

A bibliography is appended.

A new process for the chemical sterilization of drinking water in the field, M. Rhein (Ztschr. Hyg. u. Infektionskrank., 78 (1914), No. 3, pp. 562-570, flg. 1).—It was found that by the addition of 2.1 cc. of antiformin and 1.1 cc. of 25 per cent hydrochloric acid to 1 liter of contaminated water which had been filtered through wadding coli bacteria were killed in five minutes at the rate of 4,000,000 per cubic centimeter of water. The chlorin was removed from the treated water by means of a tablet containing 1.7 gm. of sodium bicarbonate and 0.45 gm. of sodium thiosulphate. The treated water had then a slightly alkaline taste, was clear and odorless, and was found safe to drink. Sodium sulphite was also found to be effective for the removal of the chlorin when bathing water was treated.

A bibliography is appended.

The manner of action of biological sewage purification media, T. Messerschmot (Ztschr. Hyg. u. Infektionskrank., 78 (1914), No. 3, pp. 475-488, figs. 2; 80 (1915), No. 3, pp. 447-456).—From a comparison made in the laboratory of the so-called absorption and nitrification theories of the action of sewage purification media, it is concluded that the nitrification theory is not entirely correct and that the action of biological filters may be explained primarily on the grounds of absorption. Nitrification is considered merely a part of the total process.

Further experiments showed that in a perfectly purified sewage the albuminous substances are so completely destroyed that they have lost their antigen character. A third set of experiments in which a natural and highly infective sewage was put through the biological filter process in the laboratory showed that under optimum conditions a complete sterilization could not be obtained.

A bibliography is appended.

A new type of trickling filter, G. G. NASMITH (Surveyor, 51 (1917), No. 1303, pp. 4, 5, fig. 1).—Experiments on a trickling sewage filter made of wood lath are reported.

"The laths of the lowest layer were laid parallel to one another, the spaces between the laths being a little less than the width of the laths themselves. A second layer was laid on top of this and at right angles to it, with the same interspace. A third row was laid parallel to the bottom row, but in such a manner that the laths covered the spaces left between the laths of the lower

series. In this way a filter 4 ft, in depth was constructed in which the sewage in order to reach the bottom had to flow over a very large surface of filter. Air could enter from all sides and the top through the regular channels provided....

"Sedimented sewage was allowed to trickle over the surface of this lath filter. In less than a month the filter was mature, and the results obtained thereafter exceeded all expectations. Where the standard type of stone filter, operated side by side with it as a control, treated 2,000,000 gal, of sewage per acre per day, the lath filter treated 6,000,000 gal, and yielded a nonputrescible effluent. This lath filter has now been in continuous use for 3.5 years and has never failed to give satisfactory results."

Satisfactory results were also obtained with a brushwood filter which within two months was treating sewage at the rate of 6,000,000 gal, per acre per day,

Brushwood as a medium for sewage filters, G. Phelps (Canad. Engin., 32 (1917), No. 6, pp. 117-120, figs. 6; Surveyor, 51 (1917), No. 1312, pp. 254, 255).— Experiments using brushwood and washed and graded steel slag as filter media are reported. The depth of medium in each case was 5.5 ft., both filters being 50 ft. in diameter.

"After two months' working, the brushwood had become thickly coated with gray slime and a very satisfactory effluent was obtained, and from that time on the flow to the filter has been periodically increased up to the present average rate of 7,250,000 gal. per acre per day. . . . Witch-hazel was found to be the best material for making up, but almost any kind of brush is suitable provided no dead wood is used. It requires to be cut in the fall or early spring when no leaves are on."

The slag filter "was started at a rate of 1,250,000 gal, per acre per day and worked up to 2,500,000 in six months. The rate was increased for a short time to 3,000,000, but this resulted in clogging and ponding on the surface and the rate had consequently to be reduced. The effluent from this filter has always been satisfactory, but its capacity is limited to about 2,000,000 gal, per acre per day, the rate at which the sewage will pass through without clogging.

"The effluent from both filters contains usually from 0.1 to 0.2 cc. of sediment per liter. This is a fine humus which is settled out by a half-hour retention in tanks. It is liable to increase with sudden rushes of storm water but is easily got rid of."

Analyses of samples of effluent from both filters "show that nitrates are not formed in the brushwood as readily as in the slag filter, which is no doubt due to the rapidity with which the sewage passes through the brushwood... The open nature of the brush allows good aeration, and it is very efficient when working at a high rate of flow. The rotary distributor also seems well adapted for this type of filter. It gives a good distribution, does not require a great deal of attention, and requires only about a foot of head for its operation....

"Brushwood shows itself to be particularly suitable as a medium for inducing the slimy growth characteristic of sewage filters. The thick coating of this slime over every particle of the brush is in marked contrast to anything that can be seen on a medium such as stone or slag. . . . To engineers constructing filters of this type, it is recommended that they be made at least 7 ft. deep if possible, and made up to this depth again when the bed has been in work for 12 or 18 months, in which time it will have shrunk down considerably."

Regulations respecting highways, 1916, F. G. Macdiarmid (Ann. Rpt. Dept. Pub. Highways Ontario, 1916, App., pp. 11).—The text of the regulations is given.

Intelligent use of road oil reduces maintenance, T. R. Agg (Engin. News-Rec., 78 (1917), No. 8, pp. 412, 413, figs. 4).—It is pointed out that the use of road oil is of little actual value unless good drainage is provided. All soils are benefited, but under Iowa conditions the gumbos give the best results.

Colorimetric test for organic impurities in sands, D. A. ABRAMS and O. E. HARDER (Struct. Materials Research Lab. [Lewis Inst], Circ. 1 (1917), pp. 7; abs. in Engin. and Contract., 47 (1917), No. 12, pp. 273).—A detailed description of the field and laboratory methods for the colorimetric test for organic impurities in sand.

"A sample of sand is digested at ordinary temperature in a solution of sodium hydroxid (NaOH). If the sand contains certain organic materials, thought to be largely of a humus nature, the filtered solution resulting from this treatment will be found to be of a color ranging from light yellow up through the reds to that which appears almost black. The depth of color has been found to furnish a measure of the effect of the impurities on the strength of mortars made from such sands. The depth of color may be measured by comparison with proper color standards."

Effect of water on the strength of concrete, D. A. ABRAMS (Concrete Highway Mag., 1 (1917), No. 4, pp. 5-7, fig. 1; abs. in Engin. and Contract., 47 (1917), No. 18, pp. 422, 423, fig. 1; Engin. News-Rec., 78 (1917), No. 4, p. 206, fig. 1).— The results of compression tests on 6 by 12 in. concrete cylinders made in mixes ranging from 1 part cement and 9 parts aggregate to 1 part cement and 2 parts aggregate by volume are summarized.

"These tests show that the effect of proportional changes in the mixing water is approximately the same for all mixes of concrete, . . . The amount of water which gives the maximum strength in concrete produces a mix which is too stiff for most purposes." The following table, based on the experiments, is given to indicate the approximate quantities of water which should be used for mixes commonly employed in concrete road construction:

# Concrete road mixtures.

Mix.		Approxi	mate mix a expressed.	Water required per sack of cement.		
Cement.	Volume of aggregate after mixing.	Coment.	Aggr	egate.	Minimum.	Maximum.
			Fine.	Coarse.		
1 1 1	5 43 4	1 1 1	2 2 1 1	4 3 3 24	Gallons. 6 53 54 5	Gallons, 61 63 6 5

Bearings for agricultural machinery, V. W. Page (Amer. Thresherman, 19 (1917), Nos. 9, pp. 44-46, figs. 3; 10. pp. 16-18, figs. 4).—This is a discussion of the design and purpose of bearings for agricultura! machinery.

Review of mechanical cultivation, M. RINGELMANN (Bul. Soc. Encour. Indus. Nat. [Paris], 127 (1917), No. 1, pp. 197-218. figs. 15).—This is a review of the status of mechanical cultivation in Europe, with special reference to wartime conditions. Typical tests of different outfits are discussed.

A press for the Georgia carrier, M. A. BLAKE and H. C. HAINES (New Jersey Stas. Circ. 64 (1917), pp. 8, figs. 4).—This circular describes and diagram-

matically illustrates a press designed at the station for use in pulling down into place the covers of peach shipping crates for proper nailing.

The drying of potatoes, C. Dantin (Génie Civil, 70 (1917), No. 11, pp. 171-175, figs. 10).—Apparatus for the drying of potatoes is described and illustrated.

Some details in the construction of wooden hoop silos, I. D. CHARLTON (Washington Sta., West. Wash. Sta. Mo. Bul., 5 (1917), No. 2, pp. 20-23, figs. 4).—Brief instructions, with illustrations, for the construction of wooden hoop silos are given, together with a bill of material and costs for a 14 by 32 ft. silo of 100 tons capacity.

Housing of chickens, J. DRYDEN (Oreg. Agr. Col. Bul., Ext. Ser. 7, No. 2 (1916), pp. 18, figs. 16).—This bulletin discusses the essentials of poultry-house construction, and gives plans, specifications, and bills of materials for both portable and stationary houses.

#### RURAL ECONOMICS.

A theory of rural attitudes, L. L. Bernard (Amer. Jour. Sociol., 22 (1917), No. 5, pp. 630-649).—The author discusses certain traits of the farmer under the following topics: The lack of scientific methods in his farm operations, the lack of contact with cultural centers, the effect of geographical isolation, seasonal labor requirements, conservatism, emotionalism, and frugality. The author points out the causes for these various traits, as well as their effect upon the mind of the person living on a farm.

Farm organization, balance between crops and stock, crop rotation and labor distribution, K. C. Livermore (N. Y. Dept. Agr. Bul. 86 (1916), pp. 2432-2448, figs. 2).—The author outlines methods that may be used to measure the efficiency of the various factors affecting the farm income and cites a number of typical examples.

Minor articles of farm equipment, H. N. Humphrey and A. P. Yerkes (U. S. Dept. Agr., Farmers' Bul. 816 (1917), pp. 15).—This is a revision of circular 44 of the Bureau of Plant Industry, previously noted (E. S. R., 22, p. 492).

In the summary list of the inventories of minor equipment for 33 general farms in Ohio the articles are classified as "essential" (found on at least 20 per cent of the farms) or as "not essential but very desirable." It was found that the total value, under normal price conditions, of the essential articles amounted to \$114.70 and the other articles to \$121.15.

Food preparedness, H. R. Seager and R. E. Chaddock (Columbia [Univ.] War Papers, 1. ser., No. 6 (1917), pp. 23).—In this pamphlet, which is one of a series of war papers issued by the Division of Intelligence and Publicity of Columbia University, the authors have pointed out the decrease in the per capita production in the United States and in the exports of agricultural products, but call attention to the increase in meat products due to the slaughtering of animals already on hand. They advocate the mobilization of food supplies and an increase in production through the augmenting of farm labor, the introduction of home gardening, a guaranteed minimum price to producers, the use of war bread, and the elimination of waste.

A farm census of New York State (N. Y. Dept. Agr. Bul. 89 (1916), pp. 32).—This bulletin gives the results of a census taken by the school children in New York State during January, 1916. It describes the methods used and presents the details by counties of the results obtained.

Redistribution of farm land in France, P. DE CABAUSSEL (Vie Agr. et Rurale, 7 (1917), No. 15, pp. 257-264).—The author discusses the question of the redistribution of farm land in its effect upon the rural proprietor, the inconvenience that will be caused to the occupants by the breaking up of farms,

and the insufficiency of legislation to accomplish this purpose. He calls attention to methods being used in other countries and the difficulties likely to be experienced in determining the boundaries of farms in the territories that have been devastated by the war.

The Torrens system, E. C. Massie (Richmond, Va.: Everett Waddey Co., 1916, pp. XVII+206, figs. 25).—This volume is a manual of the Uniform Land Registration Act of Virginia and has appended the annotated act, proposel rules of court, and a complete system of forms. It also contains references to all decisions made in the United States relating to this system.

Agricultural labor, T. B. Ponsonby (Better Business, 2 (1917), No. 3, pp. 240-264).—The author discusses the methods that may be used in standardizing the activities of agricultural labor as a means of improving the conditions of rural employment in Ireland.

[Agricultural wages in Sweden, 1915] J. G. RICHERT (Arbetartillgang, Arbetstid och Arbetslön. Stockholm: K. Socialstyrelsen, 1916, pp. 39).—The author discusses wages received by various types of agricultural laborers in Sweden under the different kinds of working conditions found in that country.

The Federal Farm Loan Act and the farmer, F. B. Bomberger (Md. Agr. Ext. Serv. Bul. 4 (1917), pp. 87).—This bulletin explains the purpose and function of the Federal Farm Loan Act, and contains models of statements that may be used in making application for loans, organizing the associations, and transacting the business of local associations.

Oregon rural credits primer, H. MACPHERSON (Oreg. Agr. Col. Ext. Serv. Bul. 201 (1917), pp. 15).—The author has given answers to a large number of questions raised in his State regarding the subject of the Federal Farm Loan Act.

Organizing cooperative associations, J. E. Boyle (North Dakota Sta. Circ. 16 (1917), pp. 24).—The author explains the function of cooperative organizations, and methods of organizing, and gives a model form for the articles of incorporation and for the by-laws for a cooperative elevator, a cooperative creamery, cooperative egg association, cow-testing association, live-stock shipping association, and a potato warehouse company. There is also included text of the North Dakota law governing cooperative corporations.

[Bulk handling of wheat in the Inland Empire]. G. B. Hegardt (Portland, Oreg.: Com. Pub. Docks, 1916, pp. 40, pls. 16; appendix, pp. 61).—This is a report covering an investigation of the movement now under way to adopt the system of bulk handling of wheat to tidewater and conclusions regarding it, together with a statement of present and required terminal facilities for bulk handling and shipping. The report relates especially to conditions surrounding Portland, Oreg. It is accompanied by an appendix, bound in a separate volume, which contains evidence obtained in gathering data for the report.

Statistical information relating to stocks, cotton, grain, provisions, live stock, and seeds, 1916 (Chicago: Howard, Bartels & Co., 1916, pp. 54).—This report continues data previously noted (E. S. R., 35, p. 394), adding statistics for 1916.

[Livestock statistics of Sweden] (Internat. Inst. Agr. Rome, Internat. Crop Rpt. and Agr. Statis., 8 (1917), No. 4, p. 322).—This contains data showing for the different classes of live stock the number on June 1, 1916, December 31, 1914, and December 31, 1913.

Statistics of live stock and animal produce for the year 1916 [in Rhodesia], E. A. Nobbs and F. Eyles (Rhodesia Agr. Jour., 14 (1917), No. 2. pp. 184-188).—These pages continue the data previously noted (E. S. R., 35, p. 500).

[Agriculture in Japan] (Statis. Rpt. Dept. Agr. and Com. Japan, 32 [1915], pp. 1-130).—These pages continue the statistical data previously noted (E. S. R., 36, p. 594).

### AGRICULTURAL EDUCATION.

Agricultural education, E. TISSERAND (Bul. Soc. Encour. Indus. Nat. [Paris], 127 (1917), No. 1. pp. 56-77).—The author reviews the development and present status of agricultural education in France, and discusses its reorganization and improvement.

Among his recommendations are the reorganization of the entire agricultural education service, including all grades of institutions, and the establishment of a higher council of agricultural education, consisting of 24 members, to supervise the functions of all parts of the service. The council should comprise three sections, dealing respectively with (1) higher instruction, including the National Agricultural Institute, the national schools of agriculture, horticulture, agricultural industries, and dairying and cheese making, and agricultural instruction in the faculties of universities; (2) the practical and special schools of agriculture, farm schools, seasonal schools, winter schools, and agricultural orphanages; and (3) the departmental and district chairs of agriculture, and itinerant and home economics instruction.

The character of the higher scientific instruction of the agricultural institute should be strengthened and its equipment improved and extended. Its course of study should be so revised as to turn out graduates who will assure competent recruits for the national schools of streams and forests and of horse breeding, and to make the institute, together with the national schools of agriculture, a center for the training of professors and assistants, directors of stations and laboratories, and technical agents for the public agricultural service. The courses of study of the national schools of agriculture should also be revised.

Further recommendations include an increased number of practical schools of agriculture, conserving their character of peasant schools, the revision of their course of study and its limitation to two years, and the establishment in connection with them as well as the farm schools of wood and machine shops for the practical work of students; the development of the staff of departmental and special district professors of agriculture; the multiplication of chairs of agriculture in the lyceums, colleges, and higher primary schools, as well as of special winter schools and home economics instruction for girls in rural districts; the revision of the salaries of the scientific research and instruction staff, so that its members need not seek outside employment for a livelihood, but could give their entire time and effort to their profession; and finally the organization of correspondence courses in agriculture at the agricultural institute, the national schools, and the practical schools.

Report of the acting secretary for agriculture (education) for the year 1914-15, A. Holm (Union So. Africa, Rpt. Sec. Agr. (Ed.), 1914-15, pp. 37).—This is the third annual report of the section of the department of agriculture of the Union of South Africa which deals with agricultural education. Detailed information is given with reference to the staff, students, courses of studies, extension and experimental work, buildings and equipment, cost of education and maintenance, and finances, of each of the four agricultural schools now in operation, located respectively at Elsenburg and Middelburg in the Cape Province, Cedara in Natal, and Potchefstroom in the Transvaai. A fifth school, with accommodations for 40 students, and a farm of 4,000 acres, has been erected at Glen in the Orange Free State, but its opening has been postponed because of the financial stringency created by the war.

At the beginning of the school year 1914 there were 205 students in residence at the four schools, but a large number left during the year to join the military forces. At the beginning of the 1915 school year the attendance,

which had dropped to \$3, increased to 105, with an average age of from eighteen to nineteen years. The schools, which are located on large, well-stocked, and well-equipped farms, offer a 1-year certificate course, a 2-year diploma course, a 3-year advanced diploma course, a special course in dairying (at the Grootfontein school at Middelburg), followed by practical work in a factory dairy, a 2-week short winter course open also to women, and special short courses in the various subjects. At the request of the university council of the Cape of Good Hope, courses have been prepared and submitted for the third and fourth years at the agricultural schools for the degree of B. S. in agriculture.

Although the war and consequent disturbed conditions of the country interfered with the extension work, 190 lectures and demonstrations outside of the schools were held, attended by 7,000 people, as compared with 328 lectures and demonstrations in the previous year, attended by 20.000 people. Eleven agricultural education exhibits were made at shows, 440 farms and poultry yards were visited for the purpose of giving advice, etc.

[Agricultural instruction in the Philippine Islands], N. H. Foreman et al. (Philippine Craftsman, 5 (1916), No. 4, pp. 235-311, figs. 25).—This issue comprises the following articles: Agricultural Activities of the Bureau of Education, Results of Agricultural Education As Shown in Graduates of the Central Luzon Agricultural School, Demonstration Work in Rice Culture for Farm Schools, How Specialization in Gardening Pays, Suggestions for Primary and Intermediate Gardening Teachers, Correlation of Field and Class Work in Farming, Poultry Raising at the Santa Maria Farm School, Agricultural Instruction in the Primary Grades, Agricultural Training of Manobo Boys, Agricultural Extension in the Ilongot Settlement Farm Schools, Hog Raising at Lagangilang, Garden Days with Prizes, and Clean-up Week in Oriental Negros; an editorial on Two Kinds of Agricultural Instruction, viz, general and vocational; resolutions of the annual industrial conference held May 1-5, 1916; and notes on industrial work in the schools of the various Provinces.

Agriculture in the high school, H. N. Goddard and J. A. James (Madison, Wis.: Dept. Pub. Instr., 1917, pp. 191, figs. 24).—This bulletin has been prepared to furnish a guide to high schools giving instruction in agriculture, and especially to those that maintain four-year agricultural departments. It contains the texts of the laws relating to agricultural instruction in the schools of Wisconsin; outlines of courses of study; a discussion of general methods and lines of work, including field work, laboratory experiment and observation, class instruction, practical school and home projects, contests and exhibits, manual-training work, and community or extension work; equipment; general and topical outlines suggestive of work that should be done in farm plant life, animal husbandry, soils, farm mechanics, farm management, and manual training; and a list of agricultural literature. A list of national registry associations, standards for Wisconsin crops, and official Wisconsin score cards are appended.

[Agricultural and home economics in the public schools of New Hampshire], G. H. WHITCHER (N. H. Dept. Pub. Instr., Div. Insts., 1915-16, Nos. 53, pp. 7; 56, pp. 16, figs. 10; 57, pp. 13, fig. 1; 1916-17, 66, pp. 5).—These circulars for teachers deal with experiments in nature study, field projects, rational methods in teaching cooking, and domestic arts courses in a high-school of the usual four-year type.

Suggestive outlines of industrial courses for consolidated and rural schools (Minn. Dept. Ed. Bul. 42, rev. ed. (1917), pp. 116, figs. 29).—Part 1 of this bulletin deals with suggestive outlines for home training, which are arranged in two groups. The first group includes lessons for the entire school, comprising topics with which boys and girls alike should become familiar, such

as the preservation of food, the handling of the school lunch, the use of small tools, social customs, labor-saving equipment for farm and home, public-health questions, shelter, family income, sanitation, civic responsibilities, etc. The lessons in the second group are arranged in three plans, designed respectively for schools having one 60-minute period a week in the sixth grade and two 80-minute periods a week in the seventh and eighth grades for industrial work; those having two 60-minute periods a week in the seventh and eighth grades; and those having one 80-minute period a week in the seventh and eighth grades. The work of the sixth grade involves the principles and processes of garment making carried out with simple garments; that of the seventh grade relates to the care of the house and its equipment, laundry work, the care of children, the planning and preparation of meals, garment making, and the care and repair of clothing; the eighth grade work deals with home management, including the responsibility of the home maker, the family income, an efficient home, shelter, house planning, labor-saving equipment, cooking, planning, preparation, and serving of meals, household accounts, the care of young children and of the sick, civic responsibilities, elementary dressmaking, the study of clothing, etc.

Part 2 consists of outlines for manual training.

The organization and administration of a collegiate department in poultry husbandry, H. R. Lewis (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 3 (1917), No. 7, pp. 49-52, 53, 54).—In this discussion of the most essential factors of the successful organization and administration of a department of poultry husbandry, the author calls special attention to the importance of department individuality and unity of departmental responsibility, and of a definite, clean-cut organization. In his opinion responsibility for the policy, administration, and efficiency of all research, instruction, and extenson work should be centered in one individual, who should be professor of poultry husbandry in the college and poultry husbandman in the station. Next in line and responsible to him should be a number of scientifically trained men, viz., an instructor in the college, a research assistant in poultry husbandry, an extension specialist in poultry husbandry, and a research biologist. In order that their highly specialized activities may not result in a narrow viewpoint, it is desirable that each division head should be given some work in the other branches, that is, the instructor and research specialist should at some time during the year go around the State to do some extension teaching and thus get in contact personally with the problems of the commercial poultrymen, thereby becoming intimately associated with the questions which must be investigated and taught.

Weekly staff meetings of the department, at which the head of each division makes a written report as to the condition of the work for which he is responsible; special conference hours between the head of the department and members of the staff for the discussion of problems in detail; issuing regular departmental instructions in the forms of a single, loose-leaf note book, which can be added to from time to time; and planning and arranging all important departmental activities by means of conferences also are suggested as conducive to efficiency. Methods of keeping in touch with the results of research projects and extension activities are also suggested.

# NOTES.

Alabama College and Station.—Dr. Wright A. Gardner, formerly associate professor of botany and plant physiologist at the Idaho University and Station, has been appointed plant physiologist and head of the department of botany.

California University and Station.—Dr. Robert H. Loughridge, widely known as a pioneer research worker in soil chemistry and emeritus professor of agricultural chemistry, died July 1 at Waco, Texas.

Dr. Loughridge was the son of the first missionary to go to the Creek Nation after these Indians moved from Florida, and was born at the Presbyterian mission station at Koweta, Indian Territory, on October 9, 1843. He was educated at the mission school established by his father and entered La Grange Synodical College in Tennessee in 1860. He left college in 1862 to serve in the Civil War, and at its close became a student in the University of Mississippi. Here he became acquainted with Dr. E. W. Hilgard, with whom he was subsequently so closely associated.

Dr. Loughridge was graduated from this institution in 1871 and in 1878 received the degree of Ph. D. From 1874 to 1878 he was adjunct professor of chemistry in the university and assistant State geologist of Mississippi. Subsequently he assisted Professor Hilgard in the preparation of his report on cotton production for the Tenth Census and served as assistant State geologist in turn of Georgia, Kentucky, and South Carolina. He was also professor of agricultural chemistry of the University of South Carolina from 1885–1890, and instituted considerable experimental work with field crops, fertilizers, etc., at that institution.

In 1891 he came to the University of California, teaching agricultural chemistry and participating in the classical researches of Professor Hilgard as to the chemistry, physics, and geology of the soils of California, methods for the reclamation of alkali lands, scientific problems of the relation of the irrigation and drainage to the qualities of California soils, and the problem of maintaining and increasing nitrogen in those soils. His retirement from active service in 1909 was noted editorially in the Record (E. S. R., 21, p. 4).

Dr. Loughridge was a fellow of the American Association for the Advancement of Science and the Geological Society of America and a member of the Society for the Promotion of Agricultural Science and many other organizations. He was also the author or joint author of numerous publications.

Connecticut College and Storrs Station.—According to a note in Science, Austin C. Dunham has offered the college his farm of 130 acres at Newington for use for school purposes. About \$50,000 has been expended in improving the property, which is considered one of the best equipped in the State.

Arthur G. Gulley, for 23 years professor of horticulture, died August 16 at the age of 68 years. Professor Gulley was a graduate of the Michigan College in 1868 and received the master's degree from the same institution in 1873.

B. G. Southwick, assistant agronomist, has been appointed extension agronomist and station field agent, devoting one-quarter of his time to the station and the remainder to extension work.

Hawaiian Sugar Planters' Station.—The station has recently been provided with a building of reinforced concrete construction, which will house the business offices, the offices of the agricultural department, the office and laboratory of the entomological department, and the library. The building offers increased floor space to accommodate the growth of the station, and also provides fire-proof quarters for the station library and entomological collections, which were heretofore housed in a frame building.

Idaho University.—The department of forestry has been segregated from the college of arts and sciences, as an independent school. F. G. Miller, head of the department of forestry in the Washington College, has been appointed dean of the school and professor of forestry.

A modern horse barn 40 by 112 feet and a sheep barn 32 by 80 feet are being erected.

Purdue University and Station.—F. G. King, associate in animal husbandry, has received a commission as captain in the National Army.

Towa Station.—Dr. A. W. Dox, chief of the section of chemistry, has been granted leave of absence to accept an appointment as captain in the food division of the Sanitary Corps of the National Army.

Kansas College and Station.—Among the members of the staff engaged in military service are the following: E. N. Wentworth, professor of animal breeding; H. B. Walker, associate professor of irrigation and drainage engineering; Robert Schmidt assistant in botany; Herschel Scott, fellow in soils; Ernest E. Dale, fellow in horticulture; and C. E. Aubel, fellow in animal husbandry.

Recent appointments include K. J. T. Ekblaw as professor of farm engineering, A. C. Hartenbower as superintendent of institutes and extension schools, John H. Parker as assistant professor of farm crops, L. H. Fairchild as assistant in dairy husbandry, H. F. Lienhardt as instructor in bacteriology. W. F. Pickett as assistant in plant propagation and foreman of the greenhouse, E. C. Thurber as hog herdsman, H. H. Amos as assistant in poultry husbandry, W. L. French as specialist in agriculture in the home study department, Miss Lena L. Price as research assistant to the director of the station, W. S. Stevens as associate in stock remedy analysis, and William E. Paterson as specialist in dairy husbandry in the division of extension.

Kentucky University.—Dr. Frank Le Rond McVey, president of the University of North Dakota since 1909, has been appointed president.

Maine University and Station.—Leave of absence has been granted for the duration of the war to Drs. Raymond Pearl and F. M. Surface, for service with the statistical department of the U. S. Food Administration. Dr. H. R. Willard, of the university, and John R. Miner, of the station, are also associated in this work.

Massachusetts College.—E. L. Quaife, assistant professor of animal husbandry, has resigned to accept a position in the extension work in animal husbandry in the Iowa College.

Minnesota University and Station.—Clyde H. Bailey, cereal technologist and assistant professor of agricultural chemistry, who has been on leave of absence as chemist for the State Board of Grain Appeals, has returned as associate professor of agricultural biochemistry. Simon Marcovitch, assistant entomologist, has resigned to become head of the department of biology at the National Farm School of Pennsylvania.

Mississippi College.—J. Wendell Bailey, assistant professor in the general science school, has accepted an appointment with the Bureau of Entomology of the U. S. Department of Agriculture and is engaged in studies of insects affecting cereal and forage crops at Tempe, Ariz.

Montana Station.—B. W. Whitlock, for the past four years superintendent of the State grain laboratory of the station, has resigned to accept a position as Federal grain supervisor with headquarters at Salt Lake City. E. W. Jahnke, assistant in the laboratory, has been appointed superintendent.

Nevada University and Station.—Dr. Walter E. Clark, head of the department of political science of the College of the City of New York, has been appointed president, to take effect January 1, 1918. James B. McNair has been appointed assistant chemist in the station.

A joint study of poisonous plants has been arranged. The department of range management will take up the study of methods of handling live stock on the range for the prevention of losses due to poisonous plants. The veterinarian will study the characteristic symptoms of poisoning by various plants and will make post-mortem examinations of poisoned animals to determine the character of the injury caused by plant poisons. The department of chemistry will attempt to isolate the poison and to determine the part of the plant in which poisonous matter is most abundant and the stage of plant growth at which injury is most certain to occur.

New Hampshire College.—A. W. Richardson, instructor in poultry industry at the University of Maine, has been appointed assistant professor in charge of the poultry department, vice R. V. Mitchell. J. R. Hepler, of the Wisconsin University and Station, has been appointed assistant professor of horticulture, and H. F. Depew assistant in dairying.

New Jersey College and Stations.—F. C. Minkler, professor of animal husbandry and animal husbandman, director of the short courses in agriculture, and live-stock commissioner for the State Department of Agriculture, has resigned to accept a position in charge of live stock on a private estate in the State.

Cornell University and Station.—School and Society states that on account of the financial uncertainty caused by the war, a temporary rule has been adopted making all terminable appointments in the instruction staff for next year effective for one year only. Heretofore, instructors and assistant professors have been appointed for terms of from one to five years.

A. R. Mann has been appointed dean of the College of Agriculture and director of the station.

Chas. H. Tuck, who has been absent on leave since January, 1916, to engage in agricultural explorations in Manchuria for an American syndicate, has resigned and has been succeeded by M. C. Burritt as professor of extension teaching and vice director of extension. Other promotions include J. R. Schramm as professor of botany, R. H. Wheeler as professor of extension teaching, and H. O. Buckman as professor of soil technology.

Ohio State University and Station.—Frank Beach, assistant in horticultural extension at Purdue University, has been appointed specialist in horticulture in the university beginning July 1.

In the station Horatio Markley has resigned from the board of control to take charge of fair exhibits, vice F. M. Lutts, who has been appointed a superintendent of experiment farms. James Devol, of Marietta, has been appointed to the board of control to succeed Mr. Markley. Other appointments include the following: William H. Alexander, section director of the U. S. Weather Bureau, as climatologist; Firman E. Bear, of the College of Agriculture, as associate in soil technology (nonresident); J. T. Parsons, assistant in soil technology; O. I. Snapp, assistant in soils; J. R. Stear, assistant entomologist; I. P. Lewis, field assistant in horticulture; and M. O. Bugby, S. C. Hartman, and W. J. Smith, superintendents of experiment farms.

Pennsylvania College and Station.—Among recent appointments are the following: Effective July 1, A. A. Farnham, instructor in landscape gardening; and Grace Armstrong and Mary R. Fisher, instructors in home economics extension; July 7, Clair W. McDonald, assistant in animal husbandry; August 1, M. F. Grimes, assistant professor of animal husbandry; H. C. Yerger, jr., instructor in dairy manufacture; and J. N. Else, assistant in agronomy; September 1, H. G. Parkinson, assistant professor of rural education; Fred Hultz, assistant in animal husbandry; and W. T. White, teaching fellow in agriculture; and September 24, C. A. Hunter, assistant professor of bacteriology. G. S. Bulkley has been transferred from the dairy husbandry department to extension work as assistant professor of dairy husbandry extension. J. M. Sherman, assistant professor of bacteriology; E. O. Anderson, instructor in farm management; and H. R. Kraybill, instructor in agricultural chemistry, have resigned.

Oregon College and Station.—An apple and pear packing school was conducted by the horticultural division September 4 to 15. A short course in pruning will be offered during December.

P. M. Brandt, assistant to the dean and director at the Missouri University and Station, has been appointed professor of dairy husbandry. L. W. Wing, assistant in dairying at the same institution, has been appointed instructor in dairying. Bernard F. Sheehan, in charge of alfalfa investigations at the Iowa College, has been appointed instructor in farm crops and will assist in plant breeding at the station.

South Carolina Station.—J. L. Seal, formerly with the Bureau of Plant Industry and the States Relations Service of the U. S. Department of Agriculture, has been appointed extension pathologist and will devote his entire time to extension work in plant disease control in the State. G. M. Armstrong has been appointed instructor in the college and assistant in botany in the station, his time being equally divided between teaching and research work with cotton. W. E. Hunter, W. C. Harron, J. G. Gee, and J. L. Cathcart have been appointed graduate assistants in the divisions of botany, chemistry, and veterinary science.

The horticultural division has given intensive training to a number of the 1917 graduates of the college who are managing cooperative canneries in different sections of the State. It is stated that this has proved to be a very successful step in the food conservation campaign.

Tennessee Station.—A plant house is being built for the department of botany to be used in the further study of tomato blight, especially in the inoculation of plants with cultures of fungi isolated from blighted plants secured in different sections of the State.

The corn disease, Physoderma, has been found to be prevalent in east and west Tennessee, and the station is engaged in a campaign, in cooperation with the Plant Disease Survey of this Department, to locate the disease,

A valuable addition to the equipment of the entomological laboratory is an electric incubator, provided with an extremely sensitive thermoregulator. It has ample space for a large amount of material, also for a recording thermograph and hygrograph and thermometers, and a hygrograph by which the recording instruments are kept adjusted.

Vermont University and Station.—Dr. H. B. Ellenberger has been appointed associate professor of animal and dairy husbandry and extension specialist in dairying. B. A. Chandler has resigned as acting professor of forestry and acting forester of the station to become assistant professor of forestry at Cornell University. W. G. Hastings has been appointed professor of forestry in the university and chief forester for the State.

Virginia Station,—Recent appointments include M. O. Wilson as superintendent of the Charlotte County substation, vice A. P. Moore, resigned to enter a reserve officers' training camp; W. G. Harris as associate chemist; S. A. Wingard, previously assistant in agronomy at the Alabama Station, as assistant plant pathologist; and S. C. Harmon as assistant agronomist.

Virginia Truck Station.—J. T. Rosa, jr., has resigned as assistant horticulturist to become instructor in horticulture at the University of Missouri.

States Relations Service.—Dr. E. R. Flint, professor of chemistry in the University of Florida, has been appointed scientific and administrative assistant, succeeding Dr. E. V. Wilcox, whose resignation has been previously noted. D. W. May, agronomist in charge of the Porto Rico Station, will be located in Washington, D. C., for several months, during which time he will continue his connection with the station and will also assist in the abstracting in animal production for Experiment Station Record. H. L. Lang, of the Office of Home Economics, for several years associated with the abstracting in foods and human nutrition, has accepted an appointment as assistant professor of biology and public health in the Carnegie Institute of Technology.

U. S. Plant Disease Survey.—On July 1 there was organized as an office of the Bureau of Plant Industry, the Plant Disease Survey, with G. R. Lyman in charge. The principal objects of the survey are to collect information on plant diseases in the United States, covering such topics as prevalence, geographic distribution, severity, etc., and to make this information immediately available to all persons interested, especially to those concerned with disease control. Collaborators have been appointed from every State, and in addition, special investigations will be carried on to collect data on diseases of particular importance. The Plant Disease Survey has begun the issuing of a builetin, which will appear at frequent intervals during the crop season and will contain summaries of all the important information obtained.

New Journals.—The Journal of Dairy Science is being published bi-monthly as the official organ for the American Society of Dairy Science, formerly the Official Dairy Instructors Association. Abstracts of all papers read at the meetings of the association are to be published in the journal, and many of the more important papers and reports will be presented in full. Opportunity will also be afforded for the publication of other material. The initial number contains the address of President Pearson, of the Iowa College, at the dedication of the new dairy building at the University of Nebraska, A Preliminary Report on a Series of Cooperative Bacterial Analyses of Milk, by R. S. Breed and W. A. Stocking, a report of the committee on relations to breed associations, Specifications and Directions for Testing Milk and Cream for Butter Fat, by O. F. Hunziker, and a report of the committee on statistics of milk and cream regulations. A board of 21 editors is in charge of the journal, with J. H. Frandsen, of the Nebraska University and Station, as editor-in-chief.

Journal of the Massachusetts Poultry Society is being published bi-monthly, with J. C. Graham, of the Massachusetts College and Station, as editor. One of the primary objects is to afford a means of publishing the papers delivered at the annual poultry convention. The opening numbers also report some experimental work.

Following protests by numerous scientific organizations and others, it is announced that publication of the *Kew Bulletin*, which was suspended as a war economy measure a short time ago, is to be resumed, with some modifications as to subject matter.

## EXPERIMENT STATION RECORD.

Vol. 37.

ABSTRACT NUMBER.

No. 6.

## RECENT WORK IN AGRICULTURAL SCIENCE.

## AGRICULTURAL CHEMISTRY-AGROTECHNY.

The essentials of chemical physiology, W. D. Halliburton (London and New York: Longmans, Green & Co., 1916, 9. ed., pp. XI+324, pl. 1, figs. 71).— This is the ninth edition of this well-known work. Some additions have been made, and the revision has been thorough so as to bring the volume up to date. The work contains an introduction, elementary course, advanced course, and appendix. The subject matter is treated both from a descriptive and experimental standpoint.

International catalogue of scientific literature. **D**—Chemistry (*Internat. Cat. Sci. Lit.*, 13 (1916), pp. VIII+836).—The thirteenth annual issue of this catalogue (E. S. R., 34, p. 407). The material catalogued was received between September, 1913, and September, 1914.

Annual chemical directory of the United States, 1917, edited by B. F. Lovelace (Ann. Chem. Dir. U. S., 1917, pp. 305).—This volume contains alphabetically arranged lists of American manufacturers of chemicals and dealers in chemicals; American manufacturers of and dealers in apparatus and equipment, machinery and mechanical supplies for scientific and technical laboratories, industrial plants and organizations; professional chemical firms; Federal, State, municipal, industrial, and professional laboratories; American and foreign colleges offering courses in chemistry; experiment stations of the United States and the principal foreign stations; Federal and State officials of dairying, foods, drugs, health, and feeding stuffs; American and foreign technical and scientific societies; American and foreign chemical publications; a chemical survey of 1916; and new devices, methods, and appliances for handling industrial chemical problems.

The physical properties of colloidal solutions, E. F. Burton (London and New York: Longmans, Green & Co., 1916, pp. VII+200, figs. 18).—This monograph considers the subject under the topics of preparation and classification of colloidal solutions, the ultramicroscope, the Brownian movement, the optical properties of colloidal solutions, measurement of the sizes of ultramicroscopic particles, motion of colloidal particles in an electric field, cataphoresis, the coagulation of colloids, theory of the stability of colloids, and practical applications of the study of colloidal solutions. A list of references is appended to each chapter.

The proteins of the peanut, Arachis hypogæa.—II, The distribution of the basic nitrogen in the globulins arachin and conarachin, C. O. Johns and D. B. Jones (*Jour. Biol. Chem.*, 30 (1917), No. 1, pp. 33-38).—The globulins

arachin and conarachin previously isolated from the peanut (E. S. R., 37, p. 8) were analyzed by the Van Slyke method (E. S. R., 26, p. 22) with the following average percentage results as to nitrogen, respectively: Amid, 11.81 and 11.08; humin adsorbed by lime, 0.57 and 0.65; humin in amyl alcohol extract, 0.43 and 0.13; cystin, 0.74 and 0.75; arginin, 23.77 and 25.78; histidin, 2.78 and 2.72; lysin, 5.22 and 6.35; amino of filtrate, 53.3 and 50.23; nonamino of filtrate, 1.65 and 1.94; total, 100.27 and 99.63.

It is indicated that the relatively high percentage of lysin in the peanut proteins might make its use advantageous in supplementing diets deficient in lysin.

Levulose the preponderant sugar of apple juices, J. R. Eoff, Jr. (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 587, 588).—Tabular analytical data relative to the acidity, gravity (Brix), sucrose, levulose, and dextrose of the juices of 20 varieties of apples are reported. The data show that in all cases the amount of combined levulose exceeds the amounts of the other sugars present.

See also a previous note by Thompson and Whittier (E. S. R., 29, p. 711).

Sedoheptose, a new sugar from Sedum spectabile, I, F. B. La Forge and C. S. Hudson (Jour. Biol. Chem., 30 (1917), No. 1, pp. 61-77).

The rotatory powers of some new derivatives of gentiobiose, C. S. Hudson and J. M. Johnson (Jour. Amer. Chem. Soc., 39 (1917), No. 6, pp. 1272-1277).

The inosit phosphoric acids of cottonseed meal, J. B. RATHER (Arkansus Sta. Bul. 131 (1917), pp. 3-20).—The author has isolated from cottonseed meal as the crystalline strychnin salt an inosit phosphoric acid which corresponds to inosit triphosphoric acid,  $C_4H_4(OH)_4(H_2PO_4)_3$ . The acid was found, however, not to be of constant occurrence in cottonseed meal. From other samples of cottonseed meal an acid was isolated which agrees with the formula  $C_{12}H_{11}O_{12}P_{12}$  of the inosit phosphoric acid previously isolated from cottonseed meal and other feeding stuffs (E. S. R., 29, p. 804). "The composition corresponds equally as well to that of salts of inosit pentaphosphoric acid,  $C_6H_6(OH)(H_2PO_4)_4$ , and in view of the similarity of the formulas and the theoretical possibility of the existence of inosit pentaphosphoric acid it appears best to ascribe the latter formula to the acid."

Products prepared according to the method of Anderson (E. S. R., 31, p. 707) did not yield strychnin and silver salts which were similar to the salts of inosit hexaphosphoric acid claimed to have been isolated. "The composition of these materials agreed with that calculated for salts of inosit pentaphosphoric acid."

Experimental data are submitted in detail and discussed.

The chemistry of wood, A. W. Schorger (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 556-566, figs. 3).—Two studies are reported. The first takes up methods and results of analysis of some American species. Tabulated analytical data of longleaf pine, Douglas fir, western larch, white spruce, basswood, yellow birch, and sugar maple are reported, together with a description of the methods of analysis used. In the second paper a general discussion is given of the methods used and the analytical results obtained.

The chemical composition of the higher fractions of maple wood creosote. E. J. PIEPER, S. F. ACREE, and C. J. HUMPHREY (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 462-465, fig. 1).

On the toxicity to a wood-destroying fungus of maple wood creosote and of some of its constituents and derivatives, together with a comparison with beechwood creosote, E. J. PIEPER, S. F. ACREE, and C. J. HUMPHREY (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 566-569, figs. 2).

The application of Chodat's paracresol-tyrosinase reaction to a study of the proteolysis by microorganisms, Alice Breslauer (Bul. Soc. Bot. Genève,

2. ser., 8 (1916), No. 7-9, pp. 319-352).—From the results of the study it is concluded that the different species of microorganisms can be differentiated colorimetrically by means of the paracresol-tyrosinase reaction. Most of the amino acids give with equimolecular proportions of paracresol and tyrosinase a red color, which, in the presence of an excess of the amino acid, more or less rapidly turns blue. Glycyltyrosin and a great number of other polypeptids teact with less intensity. The rapidity and intensity of the reaction depends upon the quantity of the culture present and also upon the age of the culture. These functions vary with the different species. The nature of the culture medium was also found to influence the reaction. A parallelism between the color and the amount of gelatin liquefied was noted. Light did not affect the reaction. Low temperatures, however, greatly retarded the development of the color. The reaction was found to be valuable in detecting indol, especially when present only in very small amounts with skatol.

The relation of microorganisms to the ripening of cheese is noted.

The data are submitted in detail and discussed.

A course in food analysis, A. L. WINTON (New York: John Wiley & Sons, Inc., 1917, pp. IX+252, figs. 107).—This volume considers dairy products, meat and fish, natural vegetable foods and mill products, microscopic examination of vegetable foods, saccharine products, fats and oils, fruits, fruit products, liquors and vinegars, flavoring extracts, coffee, tea, and cocoa. Calculation tables and a list of apparatus, reagents, and practice material are appended.

The book is intended to give an introductory course in the subject prior to the use of more extensive works or to meet the needs of the general student.

A simple device for evaporating solutions to a definite volume, G. P. PLAISANCE and N. C. PERVIER (Jour. Amer. Chem. Soc., 39 (1917), No. 6, pp. 1238-1240, figs. 3).—An easily assembled apparatus and its manipulation are described in detail.

An evaporating bath of sea sand heated by steam, P. P. Peterson (Jour. Indus. and Engin. Chem., 9 (1917), No. 7, p. 686, figs. 2).—An apparatus in which the sand bath is heated by coils of pipe through which superheated steam is passed and controlled by a suitable steam trap is described.

Handling laboratory solutions by suction, C. L. Beals (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, p. 603, fig. 1).—The author, at the Massachusetts Experiment Station, describes an apparatus and its construction for obtaining solutions from large containers. The apparatus was successfully applied to measuring dilute acid and alkali solutions used in fiber determinations.

A note on an automatic suction attachment for an ordinary pipette, J. P. Schroeder (Jour. Indus. and Engin. Chem., 9 (1917), No. 7, pp. 687, 688, figs. 3).— An apparatus which consists essentially of the attachment of a stopcock to an ordinary pipette, or for automatic measurement a Gooch crucible filter tube and a stopcock, is described.

A simple device for the automatic and intermittent washing of precipitates, E. C. Lathrop (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 527, 528, fig. 1).—An apparatus which has yielded excellent results and its manipulation are described in detail.

An improved form of a fumeless digestion apparatus, J. S. McHargue (Jour. Indus. and Engin. Chem., 9 (1917), No. 7, pp. 686, 687, fig. 1).—The author, at the Kentucky Experiment Station, describes an enlarged and modified Sy fumeless nitrogen digestion apparatus (E. S. R., 28, p. 311). The apparatus is indicated as yielding excellent results.

An apparatus for the purification of mercury, H. E. PATTEN and G. H. MAINS (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 600-603, figs. 3).—

An apparatus, which has yielded satisfactory results, and its manipulation are described in detail.

Recovery of molybdenum residues, V. Lenher and M. P. Schultz (Jour. Indus. and Engin. Chem., 9 (1917), No. 7, pp. 684, 685).—The authors present a method for recovering molybdenum residues which consists of the precipitation of molybdenum sulphid by hydrogen sulphid from a solution slightly acid with nitric acid or the formation of a sulpho-molybdate solution by adding hydrogen sulphid to the alkaline solution of the "yellow precipitate" and subsequent precipitation of molybdenum sulphid with hydrochloric acid. The molybdenum sulphid when ignited yields MoO<sub>2</sub>, which is in a condition to be readily used.

When an acid solution is used the acidity should be kept between 0.1 and 0.4 per cent. In case much iron is present the sulphid should be washed with water containing hydrochloric acid. When the "yellow precipitate" is dissolved in alkali any iron, if present, will be precipitated as the hydroxid and can be easily removed by filtration.

Determination of total nitrogen, G. H. G. Lagers (Chem. Weekbl., 14 (1917), No. 21, pp. 492-499).—Experimental data on the determination of nitrogen in various fertilizers containing both organic and inorganic (nitrate) nitrogen by the method of Jodibaur, the Kjeldahl method, the Kjeldahl method plus zinc, the Kjeldahl method plus ferrous sulphate, and a procedure involving the Kjeldahl and Schlösing methods are reported in tabular form.

The Jodlbaur method yielded low results in samples which contained ammonia or nitrates. Exact results were obtained, however, by a combination of the Schlösing and Kjeldahl methods in which the sample was first treated with ferrous chlorid and hydrochloric acid and then according to the regular Kjeldahl procedure.

The methods used are described in detail and the results discussed.

Nitrate determinations in the presence of chlorids, W. F. Gericke (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 585, 586).—The author, at the California Experiment Station, proposes a modification of the phenoldisulphonic acid method in which the evaporation of the solution to dryness is obviated by the use of concentrated sulphuric acid, which is added to the aqueous extract. The addition of the sulphuric acid and phenoldisulphonic acid to the aqueous solution prevents the loss of nitrates, which in the old procedure was occasioned by the addition of acid to the dry salts after evaporation. It is noted that the temperature of the final evaporation and concentration of the aqueous solution should not exceed 70° C.

Some analytical data are submitted.

A study of the determination of potash chiefly concerned with the Lindo-Gladding method, P. L. Hibbard (Jour. Indus. and Engin. Chem., 9 (1917). No. 5, pp. 504-513).—From a critical study of the method, the author has found that in preparing a solution for the determination of potash considerable variation in the volume of water used, amount and time of boiling, excess of ammonia, and time of standing after boiling but before filtering have but little effect on the results.

Higher results and fewer impurities in the solution are obtained by extraction of the material with hot water on a filter. For this extraction a tube filter was found to be much more efficient than the ordinary paper filter in a funnel.

For correct results the ignition of the ash must be so gradual that spattering does not occur. The addition of 10 mg, of sugar during the evaporation was found to be a material aid. "The final temperature need not be above a moderate red heat for a few minutes. Long heating near the fusion point of the salts causes loss of potash. A little SO<sub>4</sub> remaining as bisulphate does no harm. In

case the residue is not easily burnt white, it is best to dissolve in water and a little hydrochloric acid and filter out insoluble matter. In many cases organic matter and ammonium salts may be conveniently removed by evaporation of the solution with aqua regia." After ignition the residual salts are best dissolved by adding a few drops of hydrochloric acid and heating before adding much water.

"Separation of K<sub>2</sub>PtCl<sub>6</sub> requires certain conditions for an accurate result. Concentration of potassium at time of adding platinum must be low enough so that no K<sub>2</sub>PtCl<sub>6</sub> is precipitated at once. Free sulphuric acid, nitric acid, or organic matter must not be present. The amount of platinum used should be only slightly in excess of that necessary to combine with all the potassium. Excess of hydrochloric acid is unimportant. Evaporation should cease while some free hydrochloric acid still remains; if evaporation is carried too far dilute hydrochloric acid should be added and the evaporation repeated."

Five or six successive washings with 10 cc. of the wash fluids were found to be sufficient. In the presence of large amounts of sodium, potassium is better separated as cobaltinitrite than as platinichlorid. An ordinary Gooch crucible with asbestos felt was found to be most suitable and reliable for accurate work in collecting and purifying the precipitate. Drying can be accomplished at any temperature between 100 and 140° C., and is usually complete in an hour at 120°. The final weighing should not be made in less than half an hour after the removal from the oven.

The perchlorate procedure for the determination of potassium was found to be less reliable than the platinum method, and to be longer, more difficult, and more expensive in regard to the reagents.

A list of 30 references to the literature is cited.

The action of solutions of ammonium sulphate on muscovite, R. F. Gardiner and E. C. Shorey (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 6, pp. 589, 590).—Analytical data relative to the extraction of potassium from muscovite by ammonium sulphate are submitted and briefly discussed.

The influence of calcite inclusions on the determination of organic carbon in soils, E. C. Shorey and W. H. Fry (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 588, 589).—The authors report the presence of calcite inclusions in quartz of soils derived from limestones, as previously noted by McCaughey and Fry (E. S. R., 28, p. 812) and by Robinson (E. S. R., 31, p. 719). The effect of these inclusions on the determinations of the total carbon in such soils by the cupric oxid combustion method is indicated by the analytical data submitted. The inclusions were found to introduce no error when the carbon was determined by the wet oxidation method.

The subject is briefly discussed.

A new method for the determination of silicic acid (zeolitic) in soils, K. K. Gedrotts (C. Guédrottz) (Zhur. Opytn. Agron. (Jour. Agr. Expt.), 17 (1916), No. 5, pp. 400-407).—The value of silicic acid determinations in studying the transformations and origin of soils is indicated, and the disadvantages of the procedures commonly used are noted. The following procedure is described and deemed to yield excellent results:

Five gm. of the sample is treated with 10 per cent hydrochloric acid and heated in a small platinum crucible over a spread burner to a temperature not higher than 625° C. After cooling, the mass is transferred with a little water to a beaker, and 100 cc. of 5 per cent potassium hydroxid added. The material is heated on the water bath for one-half hour, filtered, and washed with 1 per cent potassium hydroxid. The filtrate is acidulated with hydrochloric acid, evaporated, and heated on a sand bath for from one to one and one-half

hours. The silicic acid becomes completely insoluble, and after the addition of water is separated by a filtration, washed free from chlorids, dried, and weighed in the usual manner.

A note on the phenolsulphonic acid method for nitrates in waters high in magnesium salts, M. S. Nichols (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 586, 587).—To obviate the precipitation of magnesium and iron hydroxids after neutralization of the excess phenolsulphonic acid, the addition of saturated ammonium chlorid solution was found to be satisfactory. This modification is deemed preferable to filtering the solution, as by the latter procedure a small quantity of the color always remains in the filter.

Note on the determination of strontium and lithium in water, S. D. AVERITT (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 584, 585).—The author, at the Kentucky Experiment Station, submits the following indirect methods.

For the determination of strontium, the weighed calcium and strontium oxids are dissolved in hydrochloric acid, reprecipitated as oxalates, and then titrated with standard potassium permanganate. For calculating the amount of strontium oxid, the following formula is submitted:

(W-CaO equivalent of KMnO, titration) 2.179=strontium oxid.

W=weight of CaO and SrO. The derivation of the formula is explained.

For the determination of lithium, the aqueous solution of the combined chlorids of sodium, potassium, and lithium is made up to a suitable volume, from which an aliquot is taken for the determination of potassium. From this determination the potassium and the potassium chlorid in the solution are calculated. The total chlorin is determined in another aliquot by titration with standard silver nitrate. The lithium chlorid is then calculated by the following formula:

NaCl equivalent of C+Cl in KCl+(W-KCl) ×2.64=lithium chlorid.

C=weight of total chlorin and W=weight of NaCl+KCl+LiCl.

Experimental data submitted indicate the accuracy of the procedures.

Improved chemical methods for differentiating bacteria of the coliaerogenes family, W. M. CLARK and H. A. LUBS (Jour. Biol. Chem., 30 (1917), No. 2. pp. 209-234, fig. 1).—A new medium for differentiating bacteria of the coliaerogenes family by accurate determination of the carbon dioxid and hydrogen ratios and its use are described. The differences in the intensities of the acid fermentations are determined by the use of the indicator method of hydrogen ion concentration.

The colorimetric determination of hydrogen ion concentration and its applications in bacteriology, W. M. Clark and H. A. Lubs (Jour. Bact., 2 (1917), Nos. 1, pp. 1-34; 2, pp. 109-136; 3, pp. 191-236, pl. 1, figs. 8).—A monographic review, including the original work on the subject by the authors.

It is concluded in general that with the improvements presented the colorimetric method for the determination of hydrogen ion concentration is applicable to routine as well as research purposes in bacteriology.

Improvements in the copper method for estimating amino acids, P. A. Kober (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 501-504, figs. 2).—Simple methods for dehydrating and weighing copper sulphate for use in making standard solutions, keeping a saturated solution of potassium iodid containing starch and acetic acid, and making a permanent suspension of cupric hydroxid are described in detail. A concise description of the procedure for amino acid determination by the copper method is included.

A simplified inversion process for the determination of sucrose by double polarization, H. S. Walker (Jour. Indus. and Engin. Chem., 9 (1917), No. 5.

pp. 490-492).—From some preliminary experimental data the following procedure was devised:

From 50 to 75 cc. of the sample used for direct polarization is placed in a 100-cc. flask and heated in the water bath to 65° C. In case a 50-cc. sample is used 25 cc. of water should be added. After removal from the bath 10 cc. of a mixture of equal volumes of hydrochloric acid (specific gravity 1.188) and water is added, the mixture allowed to cool spontaneously in the air for 15 minutes, and then in water to room temperature. It is made up to 100 cc. and polarized as usual.

A method for the estimation of levulose in presence of glucose, L. Loewe (*Proc. Soc. Expt. Biol. and Med.*, 13 (1916), No. 4, pp. 71-73).—The following qualitative test is described:

To 1 cc. of the sample, from 6 to 8 drops of orcein solution (0.2 per cent aqueous solution) and 1 cc. of 85 per cent phosphoric acid are added. The test tube is heated to boiling over a free flame and placed in a boiling water bath for ten minutes. In the presence of levulose a yellow color appears, the depth of which is proportionate to the concentration of the sugar. On cooling, a yellow precipitate settles out. Upon the addition of sodium or potassium hydroxid sufficient to neutralize the acid the yellow color changes to a distinct orange.

The development of this characteristic orange color was made the basis for a quantitative determination of levulose, using suitable standards. In the qualitative test levulose was detected in 1 cc. of a 0.005 per cent solution. Maltose, lactose, galactose, and arabinose in solutions of various strengths did not interfere with the tests. Cane sugar yielded a positive test, due to the presence of levulose, from the cleavage of the sugar in the presence of the phosphoric acid.

The determination of fat in certain milk products, C. K. Francis and D. G. Morgan (Oklahoma Sta. Bul. 114 (1917), pp. 3, fig. 1).—The following modified Babcock procedure for the determination of fat in ice cream and evaporated milk is described:

To 9 gm. of a uniform sample weighed in a 30 per cent cream test bottle from 4 to 5 cc. of a mixture of equal parts of glacial acetic and sulphuric acids is added with thorough mixing after each addition until a dark brown color develops. Two or three additions of one or two drops of concentrated nitric acid are now made and the mixture thoroughly agitated after each addition. The amount of nitric acid added may be increased, but precautions should be observed so that there is no loss through excessive foaming. When a light yellow color results the bottle is immersed in boiling water for from 3 to 4 minutes until the dark brown color returns. The mixture is then centrifugalized for 5 minutes, the bottle filled nearly to the neck with hot water, and again centrifugalized for 10 minutes. The fat column is brought into the scale of the neck with more hot water and again centrifugalized for another minute. The meniscus is reduced with glymol and the reading multiplied by two for a 9-gm. sample.

For malted milk, from 1 to 1.5 cc. at a time of a mixture of sulphuric and nitric acids (20 cc. H<sub>2</sub>SO<sub>4</sub> to 1 cc. HNO<sub>3</sub>) is added to a 4.5-gm. sample in a 30 per cent cream test bottle until a light yellow color is obtained. About 15 or 20 cc. of the acid mixture is usually required. The bottle is then immersed in boiling water until a dark brown color develops. A mixture of sulphuric and nitric acids (10 cc. H<sub>2</sub>SO<sub>4</sub> to 2.5 cc. HNO<sub>3</sub>) is added, 1 cc. at a time, with thorough shaking after each addition, until a light red color is developed. It is again immersed in boiling water until the dark brown color returns, centrifugalized for 5 minutes, hot water added, and again centrifugalized for 2

minutes. The fat column is then measured as usual and the reading multiplied by four.

For dried milk from 5 to 6 cc. portions of concentrated sulphuric acid are added to a 4.5-gm. sample until a dark brown color develops. The sulphuric-nitric acid mixture used for malted milk is then added, 0.5 cc. at a time, with thorough agitation, until a light red color results. The material is then immersed in boiling water until the dark brown color returns, more of the acid mixture added until the light color is produced, and again immersed in boiling water until the dark brown color reappears. The procedure is then carried out the same as for malted milk.

Experimental data submitted indicate uniformly higher results with the proposed procedure than with the Röse-Gottlieb method. Directions for the preparation of the samples of the various products, together with a graphical chart showing the variation in the fat content of 75 samples of ice cream, are included.

The determination of water soluble fatty acids in butter and other fats, M. Kauffman (Chem. Weekbl., 14 (1917), No. 16, pp. 364-367).—The following procedure, which is deemed to yield accurate results and to be much simpler than the usual procedure, is described:

One gm. of the sample is treated in a 200-cc. flask with 50 cc. of 13/100-normal alcoholic potash solution. After saponification under a reflux condenser, a small amount of water at about 90° C. and 50 cc. of 15/100-normal sulphuric acid are added. After cooling, the volume is made up to 200 cc., the liquid filtered, and 100 cc. of the filtrate titrated with tenth-normal alkali, using phenolphthalein as indicator. An excess of acid should be present to insure complete liberation of all the fatty acids and a proper correction for the amount added made.

Analytical data submitted indicate the accuracy of the procedure.

The correction required in applying the Babcock formula to the estimation of total solids in evaporated milk, O. L. Evenson (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 499-501).—Experimental data submitted show that the Babcock formula (E. S. R., 8, p. 721) can not be applied directly to the determination of total solids in evaporated milk at either 5° C. or at 37 to 40° when exact results are desired. The formula

$$T = \frac{L-1.8}{4} + 1.2 \times percentage$$
 of fat

is submitted for obtaining results which are comparable with those obtained with the Babcock fermula on whole milk cooled to its maximum specific gravity, and the formula

$$T = \frac{L - 0.5}{4} + 1.2 \times \text{percentage of fat}$$

for milk kept at 37 to 40° for 1.5 hours, or until there is no further change in the specific gravity.

The analysis of desiccated milk.—Determination of moisture and fat, C. PORCHER (Ann. Falsif., 9 (1916), No. 97-98, pp. 450-456).—The best procedure for the determination of moisture was found to be desiccation over phosphorus pentoxid for 48 hours, or 72 hours if necessary. Drying over sulphuric acid was found not to be satisfactory, and drying over calcium chlorid to be very slow. Ordinary drying in a steam oven caused a brown coloration in the material and an apparent change in some of its constituents.

The Röse-Gottlieb procedure was found to be entirely satisfactory for the determination of fat. Direct extraction with ether, however, consistently yielded low results.

The index of refraction of olive oil in relation to acidity and rancidity, A. Cutolo (Staz. Nper. Agr. Ital., 49 (1916), No. 7-8, pp. 377-387).—Data relationships of the control of the c

tive to the acidity and index of refraction of 15 samples of oil from different Italian Provinces are submitted in tabular form.

The results show in general that where the acidity is less than 2 per cent the index of refraction is nearly always 63. With increasing acidity there is a decrease in the index of refraction. The index of refraction was also found to increase with the rancidity.

The identification of emodin-bearing drugs, W. S. Hubbard (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 518-521).

The biochemistry of tobacco.—I, Critical examination of methods for determining nitrogenous substances in tobacco leaves, G. Paris (Staz. Sper. Agr. Ital., 49 (1916), No. 7-8, pp. 405-424).—The author examined the various methods for determining ammonia, amid, and nicotin nitrogen in tobacco, and submits the methods which he has adopted for the continued study of the subject.

The drying of fruits and vegetables, PEABL MACDONALD (Penn. State Col. Ext. Circ. 61 (1917), pp. 12, figs. 10).—This circular gives brief directions for drying cherries, currants, huckleberries, apples, pears, quinces, peaches, shelled peas and beans, green string beans, corn, and pumpkins, together with methods of preparing dried fruits and vegetables.

The influence of nitrogenous substances on the fermentation of fruit wines, H. MÜLLER-THURGAU and A. OSTERWALDER (Landw. Jahrb. Schweiz, 31 (1917), No. 1, pp. 44–98, flgs. 4).—In the study reported it was found that, in cases where the fruit juices were fermented only by the organisms that were present on the fruit and without the addition of nitrogenous substances, there was great variation in the fermentation, not only in the time of beginning, but also in intensity. Even though the fermentation was slow where no pure yeast or nitrogenous material was added, all the juices proceeded to complete fermentation. Retardation of the fermentation in most of the juices is attributed to the small amount of assimilable nitrogen present, as was indicated by the addition of various materials.

The addition of ammonium chlorid stimulated the fermentation in juices to which no pure yeast had been added. The stimulation varied in the different juices, and also with the amount of ammonium chlorid added, and it was evident only after the yeast cells had multiplied and required more nitrogen. The addition of ammonia either exercised no influence or had an inhibitory action on the fermentation. The influence of ammonium phosphate showed no appreciable difference from that of ammonium chlorid.

The use of pure yeast always stimulated the fermentation. The results of the use of nitrogenous adjuvants with the pure yeast were similar to those obtained in the autofermentation experiments, the effect, however, being somewhat greater.

The addition of the nitrogenous substances to grape fermentations exercised no stimulating action. A greater number of yeast cells and a marked improvement in their general condition was observed in the cases where nitrogenous substances were used.

Chemical data relative to acid formation and other fermentation data are submitted in tabular and graphical form and discussed.

Chemical control in cane sugar factories, H. C. PRINSEN GEERLIGS (London: Norman Rodger, 1917, rev. and enl. ed., pp. XII+140, fig. 1).—This volume considers analytical methods, determination of quantities, stock taking, various calculations, factory and laboratory instruments, tables, and models of books.

[Report of the] bacteriological department, W. L. Owen (Louisiana Stas. Rpt. 1916, pp. 11-15).—Continuing work on the deterioration of sugars and the principal factors affecting it (E. S. R., 35, p. 316), a number of samples were

inoculated in duplicate and a triplicate portion retained as a control. Only 10 per cent of the inoculated samples showed a greater deterioration than the controls. The results indicate that "the original infection of the majority of these samples was sufficient to cause their deterioration when suitable conditions for this action obtained."

Experiments conducted to determine the relative rate of deterioration of sugar with varying amounts of absorbed moisture showed that deterioration occurred only in samples having a factor higher than 0.25.

In a study to determine the relations between the rate of deterioration and the density of the films of molasses surrounding the sugar crystals a series of sugars was used which had factors of safety varying from 0.136 to 0.677, with molasses films varying in density from 69 to 79° Brix. The samples were stored for three months and a percentage deterioration was noted of 0.7 on a sugar with a factor of 0.677, 0.6 on a sugar with a factor of 0.369, and 1.42 with a sample having a factor of 0.472. The small deterioration on the sugar with the factor 0.677, which would ordinarily be considered very unsafe, is indicated as being probably due to the lack of certain impurities usually present in plantation granulated sugar.

Experiments on the influence of cold storage on the keeping of sugars suggested the possible cold-storage warehousing of white sugar. In a further study of the species of microorganisms causing the deterioration of sugar, the 18 bacterial cultures previously isolated showed a great variation in deteriorative power, some cultures having as much as four times the deteriorative power of others. Only two of the 20 yeast cultures isolated showed any inverting power, and this was very slight when compared to the action of the bacterial species. "Mixed inoculations of torula and bacteria invariably resulted in a deterioration greater than that produced by the torula, and much less than where pure cultures of bacteria were introduced alone. No symbiotic relationship between the two is therefore indicated in the results of these experiments.

"The maximum limit of density of the bacterial cultures was found to be between 60 and 72° Brix, while no limit has yet been found for the activity of the torula in fermenting invert sugar. Above 65° Brix the action of the torula upon sugar solutions containing both sucrose and invert sugar is exclusively confined to the latter, thus explaining the decrease in invert sugar during the storage of sugars with low factors of safety. The bacterial species associated with the deterioration of sugars have a very low minimum nutrient requirement. Standard granulated sugar and distilled water in a 35 per cent solution showed a loss of sucrose 2.69 per cent when inoculated with cultures of deteriorative bacteria. Plantation granulated sugar showed a loss of 2.9 per cent under the same condition. The addition of 1 cc. of a 1:1,000 molasses solution to 100 cc. of the standard granulated sugar solution gave a deterioration of 2.8 per cent, while the same addition to the plantation granulated resulted in a deterioration of 4.9 per cent. The addition of 1 cc. of a 1:1,000 dirt suspension caused a deterioration of plantation granulated of 8.3 per cent. These experiments emphasize the importance of cleanliness in the manufacture of white sugar of keeping qualities."

Experiments to determine acquisition of deteriorative power by the same species of bacteria as those found in sugar, but isolated from other products, showed in one case an increase in deteriorative power of about 1,100 per cent when grown for successive generations in sugar solution. "This would indicate that the most active infection of sugar comes from old sources of contamination in the house, rather than from the dirt immediately introduced into the juice from the soil adhering to the cane."

In experiments made on the retention of microorganisms contained in their respective massecuites by unwashed sugars, the results showed that on an average 13 per cent of the microorganisms of the massecuite were retained by the sugar crystals. They were reduced approximately one-half by washing.

The chemical changes which are caused by defecation of sorghum juice for sirup manufacture, A. K. Anderson (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 492-499).—The results of a study by the author at the Minnesota Experiment Station which included both factory and laboratory trials show that the acidity of the juice of sorghum cane decreases during defecation and increases during evaporation with the lime and phosphate methods. The acidity was found to vary inversely with the amount of lime used. The volume of the lead subacetate precipitate is not considered a good indication of the efficiency of defecation. In cases of high acidity there is a large precipitate. The ash content was found to increase after lime had been added. In the phosphate method a decrease in the amount of ash was noted. Calcium oxid increased during defecation and decreased during evaporation. An apparent increase in sucrose and decrease in reducing sugar was observed during defecation.

"The nitrogen content decreases during defecation. In cane which has stood after being cut the nitrogen is changed to a nonprecipitable form which is not removed by defecation. Solids-not-sugar decrease during defecation and evaporation, the larger decrease being during the latter process. The color of the juice is not darkened materially until more than the theoretical amount of lime has been added. The amount of lime to produce alkalinity is 2.2 times the theoretical amount.

"Acidity in sirups varies inversely with the amount of lime used. In sirups the total ash, insoluble ash, and calcium oxid increase with the amount of lime added. Sucrose increases and dextrose decreases with the amount of lime used. Crystallization is due to a high percentage of dry matter, a relatively high sucrose content, and a juice relatively free from 'gummy materials.' It occurs most frequently in samples where lime was used in defecation. The darkness of color of a sirup varies directly with the amount of lime used in defecation and with the time required for evaporation.

"The phosphate and lime methods give the best tasting sirups. For economic reasons the lime method is considered the better to use. The theoretical amount of lime gives proper defecation with the minimum darkening of the juice. The titration of the juice is an efficient method of factory control."

The data are submitted in tabular form.

Sugar-beet sirup, C. O. Townsend and H. C. Gore (U. S. Dept. Agr., Farmers' Bul. 823 (1917), pp. 13, figs. 9).—Detailed directions for growing sugar beets for sirup and for making a sirup from the beets are given. The preparation of the sirup consists in extracting the sliced beets with water at from 70 to 80° C. (158 to 176° F.), and evaporating the extract to the desired consistency. The sirup, although dark in color, is indicated as being very palatable and nutritious and to be easily prepared.

Some American vegetable food oils, their sources and methods of production, H. S. Balley (U. S. Dept. Agr. Yearbook 1916, pp. 159-176, pls. 4).—This article describes the commercial methods for producing olive, cottonseed, peanut, and corn oils, and their uses.

Brazilian oilseeds, E. R. Bolton and Dorothy G. Hewer (Analyst, 42 (1917), No. 491, pp. 35-45, pl. 1).—Tabulated data of the physical and chemical constants of the oils of the seeds of 10 palms and the oils of 10 other oilseeds found in Brazil are submitted. Brief botanical notes on the seeds, together with notes on the properties of the oils, are also given.

The natural accelerator of Para rubber, H. P. Stevens (Jour. Soc. Chem. Indus., 36 (1917), No. 7, pp. 365-870).—Experimental data are submitted which show "that the rapid curing property of matured coagulum is due to organic nitrogenous bases formed during putrefaction, as small quantities of these bases can be extracted from the rapidly curing rubber which has undergone putrefaction while only a trace can be extracted from the ordinary pale crêpe." Similar bases were extracted from the residual liquors. Very small amounts of these bases were found to exert a marked effect in promoting vulcanization.

#### METEOROLOGY.

Hail in the United States, A. J. Henry (U. S. Mo. Weather Rev., 45 (1917), No. 3, pp. 94-99, pls. 5).—This article reviews geographic, seasonal, and general distribution of hail in the United States and discusses theories of hail. It is based upon 167 records covering an area of 3,026,789 square miles.

"The region of most frequent occurrence, four or more storms per year, is in southeastern Wyoming and eastward therefrom, including the western portions of Kansas, Nebraska, and Oklahoma. Adjoining this region of maximum frequency, especially to the eastward, the average number of storms per annum decreases to three. . . .

"Hail in the United States is, in general, a phenomenon of the warm season, the only notable exception being along the immediate Pacific coast from San Francisco northward. On that strip of coast hail occurs chiefly from November to March, a season that is substantially the same as that of the rains in that part of the United States. . . . Practically no damage to agricultural crops by hail is possible in the Pacific Coast States and only small damage is possible in the Gulf States both by reason of the infrequency of the phenomenon and the absence of crops at the time of greatest frequency. In Kansas, Nebraska, South Dakota, western Iowa, and northwestern Missouri hail falls at a time when destruction of crops is possible."

Reviewing the data for hail distribution in Europe, as well as in the United States, the conclusion is reached that "hailstorms over both land and water occur most frequently in temperate latitudes, the belt of greatest frequency being between the thirty-fifth and the sixtieth parallels in both hemispheres. They are infrequent in the Tropics, especially over the lowlands. In Arctic and Antarctic regions, while hail occurs more frequently than was once supposed, lack of precise observations make it somewhat conjectural whether the hail reported is graupel or true hail."

It is stated that in the United States the region of greatest thunderstorm frequency does not coincide with the region of greatest hail activity, and although hail is generally associated with tornadoes the author doubts whether the fundamental conditions for the formation of a tornado are always present in a hailstorm.

Observations on the possible influence of violent cannonading on rainfall, Sebert (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 19, pp. 703, 704).—Supplementing a previous note (E. S. R., 37, p. 418) the author calls attention to a series of observations which have been made at the Central Meteorological Bureau at Paris which may be useful in the study of this subject.

Lightning and forest fires in California, A. H. Palmer (U. S. Mo. Weather Rev., 45 (1917), No. 3, pp. 99-102, pls. 3, fig. 1).—It is shown in this article that lightning is an important cause of forest fires, and the development of the fireweather warning service, as well as the making available of facilities to subdue forest fires, is urged.

Bacteriological study of the air of Buenos Aires, H. RIGANTI (1. Conf. Soc. Sud Amer. Hig., Microbiol. y Patol., 1916, pp. 873-885, fig. 1).—Results of examinations of samples of air taken under various conditions in different parts of the city show wide variation in the germ content, depending upon conditions of temperature, illumination, ventilation, and character of the street surfaces. Samples taken from the more densely populated parts of the city, where traffic is greatest and the streets narrow and unpaved, showed a high germ content. Under similar conditions with stone pavement the germ content was slightly smaller, and it was decidedly less where the streets were paved with asphalt. The width of the streets, the height of the buildings, and the density of the population influenced the germ content to a marked extent.

Monthly Weather Review (U. S. Mo. Weather Rev., 45 (1917), Nos. 3, pp. 91-148, pls. 17, figs. 8; 4, pp. 149-201, pls. 10, figs. 25).—In addition to weather forecasts, river and flood observations, and seismological reports for March and April, 1917; lists of additions to the Weather Eureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during March and April, 1917; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 3.—Hail in the United States (illus.), by A. J. Henry (see p. 512); Lightning and Forest Fires in California (illus.), by A. H. Palmer (see p. 512); The Density of Snow, with a Note on the Disappearance and Settling of Snow in 1915–16 near Reno, Nev. (illus.), by A. J. Henry and H. F. Alciatore; A Modern Chinese Meteorological Monthly; Meteorological Observations on United States Lightships, by H. E. Williams; Avalanche Wind at Juneau, January 26, 1917, by M. B. Summers; Tornado at Cincinnati, Ohio, March 11, 1917 (illus.), by W. C. Devereaux; Tornadoes of March 11, 1917, in Montgomery County, Ohio (illus.), by R. F. Young; Unusual Hailstorm at Ballinger, Tex.; Severe Local Storm at San Diego, Cal., February, 1917; Winter of 1916–17 at Greenwich, England (reprinted); Cold Waves and Freezing Temperatures at Tampa, Fla., by W. J. Bennett; and A Skew Frequency Curve Applied to Stream Gauge Data (illus.), by W. G. Reed.

No. 4.—Equation of Horizontal Rainbows (illus.) (reprinted), by K. Otobe; Improved Kite Hygrometer and Its Records (illus.), by W. R. Gregg; Anemometer Records on a Buffalo Office Building Compared with Those Secured Near the Surface of Lake Erie (illus.), by B. C. Kadel; Some New Instruments for Oceanographical Research (illus.), by H. Pettersson; On Working Up Precipitation Observations (trans.), by H. Meyer; Tornado of April 5, 1917, at Tampa, Fla. (illus.), by W. J. Bennett; Tornado of March 23, 1917, at New Albany, Ind. (illus.), by F. J. Walz; Fish Killed by the Cold Wave of February 2-4, 1917, in Florida, by R. H. Finch; Relation between Rainfall and Run-off in Hillebrand Glen, Nuuanu Valley, Oahu, Hawaii (illus.), by R. C. Rice; and The Missouri Earthquake of April 9, 1917 (illus.), by R. H. Finch.

Meteorological, magnetic, and seismic observations of the College of Belen, Havana, 1916, L. Gangoiti (Observatorio Meteorologico, Magnetico y Seismico del Colegio de Belen de la Compañia de Jesus en la Habana, año de 1916. Habana, 1917, pp. 94).—Detailed daily and monthly summaries are given and the characteristic features of each month are described in notes.

Meteorology, J. B. Trivett (N. S. Wales Statis. Reg., 1915-16, pt. 6, pp. 345-414).—Detailed tabular summaries of observations at Sydney and other places in New South Wales during 1915 on temperature, pressure, precipitation, and wind are given.

#### SOILS—FERTILIZERS.

Edgar County soils, C. G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE, and F. W. GARRETT (Illinois Sta. Soil Rpt. 15 (1917). pp. 56, pls. 2, figs. 8).—Edgar County is located in the central eastern border of Illinois and lies principally in the early Wisconsin glaciation, with the southern part in the lower Illinoisan glaciation. The topography varies from flat to slightly rolling. The southeastern part is quite hilly.

The soils of the county are classed as upland prairie soils rich in organic matter, upland timber soils, terrace soils, and swamp and bottom lands. The brown silt loam upland prairie soil covers 52.37 per cent of the area, and the yellow-gray silt loam upland timber soils, 19.17 per cent.

Soil survey of Clinton County, Iowa, H. W. Hawker and F. B. Howe (U. S. Dept. Agr., Adv. Sheets Field Oper., Bur Soils, 1915, pp. 64, pls 3, fig. 1, map 1).— This survey, made in cooperation with the Iowa Experiment Station, deals with the soils of an area of 442,240 acres on the central eastern border of Iowa. "The county comprises three physiographic divisions, a plain of Kansan drift covered by Mississippi loess in the northern and western parts of the county, a plain of modified Iowan drift in the southern part, and an alluvial plain adjoining the Mississippi River and its tributaries in the county. . . .

"The soils of the county are derived mainly from loess, glacial drift, and alluval deposits." Including river wash and muck, 24 soil types of 13 series are mapped, of which the Memphis, Muscatine, and Carrington silt loams cover 29.2, 22.2, and 17.1 per cent of the area, respectively.

The soil resources of Maryland, A. G. McCall (Rpt. Md. Agr. Soc., 1 (1916), pp. 211-224).—This is an address delivered to the Maryland Agricultural Society in which some of the problems concerning the maintenance of the fertility of Maryland soils were discussed on the basis of experience at the Maryland Experiment Station.

Soil survey of Schoharie County, N. Y., E. T. Maxon and G. L. FULLER (U. S. Dept. Agr., Adv. Sheets Field Oper., Bur. Soils, 1915, pp. 34, pls. 4, flg. 1, map 1).—This survey, made in cooperation with the New York State College of Agriculture, deals with the soils of an area of 396,800 acres in eastern New York. "The topographic features are the rolling uplands in the northern part of the county and the rugged mountainous section in the southern part."... "Practically the entire county, with the exception of the extreme northeastern part, is adequately drained."

The soils are grouped as ice laid, stream terrace, lake laid, and alluvial soils. Including muck, rough stony land, rock outcrop, and meadow, 22 soil types of 14 series are mapped, of which the Lordstown stony silt loam and the Volusia silt loam cover 46.4 and 10 per cent of the area, respectively.

Geology of southern Ohio, W. Stout (Geol. Survey Ohio, 4. ser., Bul. 20 (1916), pp. 723, pls. 35).—This report, including Jackson and Lawrence Counties and parts of Pike, Scioto, and Gallia, contains information which should be of value in a study of the soils of Ohio.

Soil survey of Fairfax and Alexandria Counties, Va., W. T. CARTER, JR., and C. K. Yingling, Jr. (U. S. Dept. Agr., Adv. Sheets Field Oper., Bur. Soils, 1915, pp. 43, pls. 4, flg. 1, map 1).—This survey deals with the soils of an area of 287,360 acres in extreme northeastern Virginia, the topography of which ranges from gently undulating to very rolling and hilly, being predominantly gently rolling. Drainage is said to be good throughout. The western two-thirds of the area lies within the Piedmont plateau province and the eastern third within the Coastal Plain province.

The soils are of residual, sedimentary, and alluvial origin. Including clay pits and tidal marsh, 26 soil types of 19 series are mapped, of which the Chester and Manor loams cover 23.9 and 22.8 per cent of the area, respectively.

A study of the principal plantation soil types as found on the Island of Hawaii, P. S. Burgess (Hawaii. Sugar Planters' Sta., Agr. and Chem. Bul. 45 (1917), pp. 100, pl. 1, figs. 3).—This bulletin discusses the mineralogy, chemistry, physics, and biology of soils in general and deals with those of the Island of Hawaii in particular. The soils of the island are classed physically as high humus clay and silty clay loams. Colloidal aluminum and iron hydroxids are said to give the soils their apparent clayey character.

"The hygroscopic coefficients vary from 9 to over 26 per cent when determined by Hilgard's standard method, while the optimum moisture capacity averages about 45 per cent of the dry weight of the soils. The 'free water' varies from 15 to 38 per cent, while the maximum moisture-holding capacity is in all cases well above that for average mainland soils. These soils do not usually cake badly unless thoroughly puddled. When worked under optimum conditions they are fluffy and show good tilth...

"The soils, with but few exceptions, are high in total nitrogen, but its availability is universally low. The same is more or less true of phosphoric acid. Potash, both total and available, is high in all of the soils examined except in those of the Hilo district.... The amounts of total and available soil potash follow with surprising regularity the amounts of total potash as determined in the final molasses and in the molasses ashes from the mills of the several plantations. The total lime figures vary from over 5 per cent in the alkaline Kau soils to less than 0.2 per cent in acid Hamakua....

"The lime requirements for the surface soils vary from 1 ton of calcium carbonate to 11 tons, depending on location. . . . The amounts of alkali salts (the chlorids, carbonates, and sulphates of sodium) are in all cases negligible. All of the surface soils are fair ammonifiers."

Six series of nitrification experiments are also reported. "In the first, the soils received no additions of nitrogen but were incubated under standard conditions of moisture and temperature to ascertain the nitrifiability of their own organic nitrogen. In the second, ammonium sulphate was added; in the third, dried blood; in the fourth, dried blood plus sufficient calcium carbonate to exactly neutralize acidity; in the fifth, dried blood plus gypsum; and in the sixth, dried blood plus reverted phosphate."

It was found that "considering the large quantities of total nitrogen which these soils contain, the absolute amounts and the percentages of it nitrified are very low. Ammonium sulphate nitrogen is nitrified approximately twice as fast as dried blood nitrogen. As an average for the soils of the entire island, the addition of lime doubles the nitrification of dried blood. In some instances it multiplies it by three and four. Gypsum has practically no effect upon nitrification in these soils. In some instances a loss is recorded. Reverted phosphate increases nitrification by approximately 35 per cent.

"Nitrogen fixation as determined both by solution and by soil culture methods is fair in Hawaii soils. Azotobacter forms are well distributed. Three different species (A. chroococcum, A. vinelandii, and A. vinelandii, n. sp. ?) were isolated in pure cultures and tested for nitrogen fixation in both solutions and soils."

A discussion of the analytical methods used in this work is appended.

Method of botanical soil investigations on the Voronezh Zemstvo Experimental Field, S. K. CHAÎNOV and S. S. MUSHCHENKO (Metodika Pochvenno-Botanicheskikh Izsliedovanii na Voronezhskom Opytnom Polie Gubernskago Zemstva. [Voronezh]: Voronezh Prov., 1915, pp. V+17).—The method used con-

sists primarily of determining the relation of relief to soil characteristics on every section of a field. The soil characteristics are determined by the morphology; botanical growths; the relation of climate to soil temperature and moisture; and physical, mechanical, and chemical composition.

The degradation of the chernozems of the western part of the Northern Caucasus, S. A. IAKOVLEV (Pochvoviedienie (Pédologie), 16 (1914), No. 4, pp. 1-20; 17 (1915), No. 1, pp. 1-35).—The chernozem soils of the region are discussed with reference to mechanical and chemical composition.

Soil flora studies.—I, The general characteristics of the microscopic flora of soil: II, Methods best adapted to the study of the soil flora, H. J. Conn (New York State Sta. Tech. Bul. 57 (1917), pp. 3-42).—This is the first and second of a series of five reports on a study conducted for eight years on the microscopic flora of various New York State soils, in which determinations of the total number of bacteria have been made by the plate method. About 1,000 pure cultures of different organisms were isolated and their general characteristics studied.

Nonspore-forming bacteria (mostly immotile rods) were found to be the most abundant of all soil microorganisms. Next to them in abundance were the various types of Actinomyces. Certain spore-forming bacteria were also found, but not in great numbers and apparently they are not of great importance in normal soil. It is thought that soil bacteria are quite different from those found in milk, cheese, or water and that soil has its own characteristic bacterial flora.

A discussion of the methods used in these studies, the reasons for using them, and their possible development is also included.

Soil flora studies.—III, Spore-forming bacteria in soil, H. J. Conn (New York State Sta. Tech. Bul. 58 (1917), pp. 3-16, figs. 4).—This is the third of the reports of studies on the flora of New York soils and deals with the spore-forming bacteria of soil.

"Certain spore-forming bacteria are always found in soil, but in comparatively small numbers. The three most abundant spore formers found in the soils investigated are *Bacillus megatherium*, *B. mycoides*, and *B. cercus*. *B. simplex* occurs in somewhat smaller numbers. Occasionally other spore-forming bacteria have been encountered, but not in large enough numbers to be considered important.

"In the past, the spore-forming bacteria have been considered important soll bacteria. The technic used in this work, however, shows that they comprise but a small part of the flora and apparently occur in normal soil only in the form of spores. This indicates that they are ordinarily inactive in soil."

Soil flora studies.—IV, Nonspore-forming bacteria in soil, H. J. CONN (New York State Sta. Tech. Bul. 59 (1917), pp. 3-18).—This is the fourth of the reports of studies on the soil flora of New York soils and deals with the nonspore-forming bacteria in soil.

"The majority of colonies on culture plates made from soil are those of nonspore-forming bacteria. The only nonspore former that has been successfully identified with previously described species is *Pseudomonas fluorescens*. This organism is most abundant in freshly aerated soil or in soil to which organic matter has been recently added. It is known to cause ammonification in pure culture, and is therefore thought to take part in the decomposition of organic matter in soil. There are other liquefying nonspore formers in soil that seem to be closely related to *P. fluorescens*. They increase in numbers under much the same conditions and are thought to have similar functions.

"The great majority of the asporogenous bacteria of soil grow so poorly in ordinary laboratory media and produce such small noncharacteristic colonles on culture plates that little is known about them. One of the greatest present needs for a soil flora study is the development of methods by which the different species in this group may be identified.

"The numbers of the nonspore-forming bacteria in soil show greater fluctuations than do those of spore-forming bacteria or of Actinomycetes (the two other large groups of soil bacteria). High numbers of nonspore formers have been especially noticed in freshly aerated and in freshly manured soil. This indicates that they are among the most active soil microorganisms."

Soil flora studies.—V, Actinomycetes in soil, H. J. Conn (New York State Sta. Tech. Bul. 60 (1917), pp. 3-25).—This bulletin completes the series of five soil flora studies and deals with Actinomycetes or the higher bacteria.

It was found that "ordinarily from 12 to 50 per cent of the colonies on plate cultures made from soil are those of Actinomycetes. Description of species of Actinomycetes is at present very difficult. The literature abounds with descriptions that have become invalidated as better methods of study have been developed. About 70 different types have been found in the soils studied. Three of them are of fairly common occurrence. One of these three, A. pheochromogenus n. sp., is considered distinct enough to be given a specific name. One of the other two types agrees in cultural characteristics with the potato-scab organism, but its pathogenicity has not yet been tested. The other common type probably is not a distinct species. . . . The significance of these organisms in soil needs further investigation. There are good indications that they are active as well as numerically important."

Are all the soil bacteria and streptothrices that develop on dextrose agar azofiers? P. Emerson (Soil Sci., 3 (1917), No. 5, pp. 417-421).—Experiments conducted at the Iowa State College are reported in which it was found that 97 per cent of the soil organisms developing on dextrose agar plates were azofying bacteria. "No Azotobacter were present, showing clearly that there are a large number of organisms in the soil other than Azotobacter and Radicicola which have the power of fixing atmospheric nitrogen."

Some effects of organic growth-promoting substances (auximones) on the soil organisms concerned in the nitrogen cycle, F. A. Mockeridge (*Proc. Roy. Soc. [London], Ser. B, 89 (1917), No. B 621, pp. 508-533; abs. in Jour. Soc. Chem. Indus., 36 (1917), No. 13, p. 729).*—Experiments on the influence of so-called organic growth-promoting substances (auximones) extracted with water from bacterized peat on the nitrogen-fixing, nitrifying, denitrifying, and ammonifying bacteria of soil are reported.

It was found "that soluble humus, and especially that produced by bacterial decomposition, is a very important factor from the point of view of the activities of soil bacteria. Its effect upon the organisms appears to be largely independent of any inorganic matter which it may contain or any physical action brought about by its colloidal nature, and is shown to be due to the presence in the humus of growth-promoting substances or auximones. The influence of these auximones upon the organisms concerned in the nitrogen cycle may be briefly summed up in the general statement that they increase the rate of nitrogen fixation and nitrification, depress the rate of denitrification, and do not appreciably affect the rate of ammonification."

The organic matter of the soil.—V, A study of the nitrogen distribution in different soil types, C. A. Morrow and R. A. Gortner (Soil Sci., 3 (1917), No. 4, pp. 297-331).—Continuing previous work (E. S. R., 37, p. 121), studies conducted at the Minnesota Experiment Station are reported on the nitrogen distribution in fibrin, hydrolyzed in the presence of an ignited mineral subsoil; calcareous black peat; an acid sphagnum covered peat, hydrolyzed alone, in the presence of a mineral subsoil, and in the presence of stannous chlorid; an acid muck soil; samples of mineral surface soil representative of Fargo clay loam,

Fargo silt loam, Carrington silt loam, Hempstead silt loam, prairie covered loess, and forest covered loess; and extracts of a sphagnum covered peat soluble in (1) 1 per cent hydrochloric acid, (2) 4 per cent sodium hydroxid but precipitated by acid, and (3) 4 per cent sodium hydroxid and not precipitated by hydrochloric acid. The following conclusions are drawn:

"The figures for the ammonia nitrogen in a protein analysis are not appreciably changed when the hydrolysis is carried out in the presence of an ignited mineral soil equal to 20 times the weight of the protein material. The 'humin' nitrogen was greatly increased by hydrolysis in the presence of ignited mineral seil. The histidin fraction entirely disappeared. . . . The analysis of a pure protein in the presence of an ignited mineral soil does not give reliable results for the different fractions. Therefore, the figures obtained for the nitrogen distribution in soils are of value only when used for purposes of comparison. Such data should not be compared with analyses of pure proteins.

"Since practically all mineral soils give furfural on treatment with acid, it is very likely that a very considerable amount of the total humin nitrogen found is due to the presence of carbohydrates in the soil, which give rise to furfural during hydrolysis. This may combine with certain of the nitrogenous compounds and cause an increase in the humin nitrogen, as well as adsorb or occlude nitrogenous compounds in the 'humin' formed from furfural by polymerization.

"This investigation of the distribution of organic nitrogen in the soil has indicated a new fraction which should be recorded separately. This is the fraction of nitrogen removed from a colorless solution by calcium, iron, and aluminum hydroxids on the addition of calcium hydroxid. The nitrogen retained in this fraction must consist almost entirely of material of nonprotein origin, since the organic substances in this precipitate have been shown to be colorless organic compounds adsorbed by or combined with the metallic hydroxids. This fraction has been reported as nitrogen precipitated by calcium hydroxid.

"The true humin nitrogen remains in the residual soil after hydrolysis, but in addition nonhumin nitrogenous compounds are also retained in this fraction. The strength and volume of the hydrochloric acid used in hydrolysis has little effect on the nitrogen distribution of the hydrolysate, provided acid as strong as constant boiling acid is used, in the proportion of at least two parts of acid to one of soil. Results gained from a study of different soils indicate that the organic nitrogen dissolves during hydrolysis to almost the same extent regardless of the origin and nature of the soil. . . .

"In the comparison of the different extracts from sphagnum-covered peat the portion soluble in sodium hydroxid and not precipitated by hydrochloric acid gives a nitrogen distribution approximating very closely that of a normal plant protein. The nitrogen dissolving in the preliminary hydrochloric acid leaching shows a nitrogen distribution which is certainly not due exclusively to protein materials, e. g., an ammonia nitrogen percentage of 65.4 and amino nitrogen in the filtrate from bases of 17.11 per cent.

"The most significant fact brought out by this study is that the organic nitrogen distribution in different soil types is very uniform. This is to be expected, since it has been pointed out that the nitrogen distribution in soils is an average distribution of all the plant and animal nitrogenous products that find their way into the soil."

Further studies of the nitric nitrogen content of the country rock, R. Stewart and W. Peterson (*Utah Sta. Bul. 150 (1917)*, pp. 3-20, fig. 1).—The sub-

stance of this bulletin has been previously noted from another source (E. S. R., 36, p. 423).

The significance of nitrification as a factor in soil fertility, P. L. GAINEY (Soil Sci., 3 (1917), No. 5, pp. 399-416).—The author reviews the work of others bearing on the subject and work by himself at the Kansas Experiment Station in an effort to show that productivity in nonproductive soils, in so far as nitrogen is the limiting factor, is not limited by the processes of nitrification.

Soil constituents which inhibit the action of plant toxins, E. Truog and J. Sykora (Soil Sci., 3 (1917), No. 4, pp. 333-351, pls. 5).—Studies conducted at the Wisconsin Experiment Station on the constituents of soils which inhibit the action of plant toxins are reported. The soils used were acid Plainfield sand and acid Wabash silt loam.

"The experiments indicate that chemical reactions are probably very important factors in lessening the harmful effects of plant toxins in soils. Calcium carbonate, a very common soil constituent, inhibited to a remarkable degree the toxicity, to wheat seedlings, of copper sulphate and copper nitrate. . . . The toxic effects of the strong base guanidin were markedly inhibited by the presence of either kaolin or an acid clay soil. . . . The results of pot experiments with natural soils indicate . . . that vanillin can, at most, be but a very slight factor in soil fertility if the soil has an adequate supply of the fertility elements and is not acid in reaction. Here, again, calcium carbonate seems to inhibit or prevent the harmful effects of the toxic agent. . . . It is believed that the data presented show that, in the amelioration of toxicity in soils, chemical reactions probably play fully as important a rôle as physical phenomena such as adsorption, and possibly the former have the greater effect."

The extraction and saturation of soils with volatile antiseptics, J. P. DU BUISSON (Soil Sci., 3 (1917), No. 4, pp. 353-391, pls. 2).—Experiments conducted at Cornell University with Dunkirk clay loam and Volusia silt loam soils to determine the influence of treatment with the volatile antiseptics alcohol, benzene, ether, commercial gasoline, and toluene are reported. The treatment in general consisted in extracting and saturating each type of soil with the individual solvents.

It was found that "the application of volatile antiseptics to the soils used in this investigation gave beneficial results on the crops subsequently grown thereon." A beneficial, residual effect was observed for the second crop after the application of the antiseptics, but this was in all cases less marked than with the first cropping. Both types of soils responded to treatment, but somewhat differently.

The volatile antiseptics had a definite effect upon the ammonification and nitrification of the soil, enhancing the former and inhibiting the latter. There was a tendency to increase the water-soluble salts of the soil. The effect of the antiseptics upon the ammonifying and nitrifying processes of the soils after two crops were grown seemed to disappear. No marked differences were observed as to plant growth and biological activity between the saturation and extraction methods of applying the antiseptics to the soil. In these experiments the physical condition of the soil as indicated by its ammonification and nitrification did not seem to be the cause of the influences noted upon plant growth and bacterial action. By the extraction of soil with alcohol, a substance was removed which was toxic in water cultures but not at all toxic when in the soil itself. The development of acids in the soil as a result of some action or change of the alcohol was found to be too slight to account for the marked effects of volatile antiseptics upon plant growth and bacterial action.

It is finally concluded that "the beneficial influences obtained by treating the soil with volatile antiseptics can not be ascribed to a change in physical condition, to a suppression of some toxic material, or to a development of acids from the action of the antiseptics. The method of applying the antiseptics seems to have no marked influence upon the results obtained. The closely coordinated stimulation of plant and bacterial activity due to the treatment of the soil with volatile antiseptics points strongly toward a biological interpretation, with due regard for the chemical considerations, of the effects therefrom."

Farms, forests, and erosion, S. T. Dana (U. S. Dept. Agr. Yearbook 1916, pp. 107-134, pls. 10).—This article gives data on the injury to farm lands and agricultural and other industries of the United States resulting from erosion, floods, and washing. A direct relation between these and deforestation of the higher areas is shown.

It is concluded that "the problem of erosion and its control forms an integral part of any comprehensive plan for the development of our natural resources. If all land were put to its best use and so handled as to maintain its productivity the problem would be solved. This result can be attained, however, only by marked change in our present practice. A stop must be put to reckless destruction of the forest, to uncontrolled fires, to overgrazing, and to careless farming. For the sake of the farmer in particular and the public in general, steps should be taken to retain and restore the forest cover in the mountains under public ownership or supervision. There should be brought home to the people as a whole the extent and seriousness of erosion and the necessity for its control by the community."

Measuring the surface temperature of soil, A. A. Dobiasha (Dobiashe) (Zap. Selsk. Khoz. Inst. Imp. Petra I (Mem. Inst. Agron. Emp. Pierre I), 1 (1916), pp. 101, 102, pl. 1).—Methods of surface soil temperature measurements used in 30 years' experiments in Russia are described and compared. The methods of slightly pushing the thermometer into the surface soil or of placing it on the surface and covering it with soil were found to give inaccurate results.

In a third method three thermoelements on ebonite supports and made of thin wire were placed one below the other at equal distances of 1.5 mm. and covered with soil so that the upper one remained visible. Three mercury thermometers covered with soil and three open thermometers were placed parallel to the thermoelements. The day of test was hot and sunny and the temperature of the surface layer reached 60° C.

It was found that the mercury thermometers covered with soil showed a mean temperature some 2.4° higher than the uncovered ones. The thermoelements acted differently, the upper one showing the highest temperature and the difference reaching in some cases 5°. The temperature of the upper element reacted promptly to changes in temperature due to the passing of clouds before the sun. Only at depths of from 1.5 to 2 mm, were the temperatures recorded equal to that of the covered thermometer. It is concluded that the latter gives more accurate results, but that during strong radiation none gives trustworthy results.

Studies on soil colloids.—II, Influence of colloids on electrical conductivity of salts, M. I. Wolkoff (Soil Sci., 3 (1917), No. 5, pp. 423-430, figs. 2).—Experiments conducted at Rutgers College are reported in which fifth-normal solutions of aluminum potassium sulphate, ferric sulphate, lead nitrate, and hydrochloric acid and a saturated solution of calcium hydroxid were added to a colloidal solution obtained from a fresh clay soil.

It was found that "the inorganic colloid particles, as found in clay, especially the colloidal gels, hinder the electrical conductivity of salt solutions. The causes for such an interference lie possibly in (1) the fact that colloidal

particles moving comparatively slowly are in the pathway of the free ions, and (2) that the change of the structure of the gel at the point of coagulation results in an increase in the adsorptive capacity of colloids. The adsorption of electrolytes by the gel increases with the increase of the electrolyte present for coagulation. The coagulation of the colloidal solutions by means of certain electrolytes can be employed for separation of colloids from crystalloids, provided that only a minimum amount of electrolyte be used for a complete coagulation in order to reduce to the minimum the error due to adsorption."

Facilities for lysimeter and outdoor pot culture work at the station, J. F. BARKER (New York State Sta. Tech. Bul. 61 (1917), pp. 3-10, pls. 2, figs. 3).—The equipment is described and illustrated.

[Fertilizer experiments], B. S. EMANUEL (Svodnyi Otchet Sieti Kollektivnykh Opytov za Trekhaietie 1910–1913 g. Stavropol, Russia: Stavropol-Kavkaz. Selsk. Khoz. Opytn. Sta., 1914, pp. 39).—Fertilizer experiments on clay soil intermixed with dark loam at the Stavropol Caucasian experiment station for the years 1910 to 1913, inclusive, are reported.

It was found that phosphates generally increased the yield of all crops. Superphosphate was more effective on spring cereals than Thomas phosphate, and gave about equal results with potatoes. Sodium nitrate when used alone increased crop yields very little and when added with phosphates seemed to decrease the influence of the latter on crop yields. Potash frequently increased the yield of potatoes but when used with phosphates it decreased their effect. Phosphates increased the size of potato tubers but did not seem to affect their starch content. Broadcasting of fertilizers followed by deep plowing was apparently as effective as row fertilizing.

The stable-manure business of big cities, C. C. FLETCHER (U. S. Dept. Agr. Yearbook 1916, pp. 375-379, pl. 1).—This is a brief description of the process of collection, shipment, grading, storage, and treatment of stable manure from cities in the United States.

The effect of soil reaction on the availability of ammonium sulphate, R. C. Cook and F. E. Allison (Soil Sci., 3 (1917), No. 5, pp. 487-498, figs. 2).—Experiments conducted at Rutgers College are reported in which sand, silt loam, and sandy loam soils, with respective lime requirements per acre of 3,000, 3,000, and 4,000 lbs., were planted to buckwheat and treated with an excess of potassium and phosphorus and varying amounts of calcium oxid and ammonium sulphate.

From the standpoint of the utilization of the nitrogen applied it was found that the heavier the soil the less effect calcium oxid has in increasing the availability of ammonium sulphate. Buckwheat seemed to use ammonium sulphate almost as well in the heavier soils in the absence of lime as in its presence.

It was further found that "small applications of calcium oxid produced practically as large yields of buckwheat as where enough lime was added to neutralize all of the acidity or make the soil distinctly alkaline. Buckwheat grown on the more acid soils usually showed a higher percentage of nitrogen but the total yield of the crop was smaller. For this reason the recovery of the nitrogen from the more acid soils in many cases was as great as, or even greater than, that from the alkaline soils.

"The beneficial effects of calcium oxid on acid soils were much more noticeable on the sandy soils than on the silt loam. The addition of calcium oxid to acid soils allows the soil nitrogen to be made available to such an extent as to supply the needs of the crop. Hence, the use of ammonium sulphate on alkaline soils may produce a smaller increase in yield over checks than where the same amount of the fertilizer is added to an acid soil.

"Buckwheat is able to utilize the nitrogen from ammonium sulphate at an acidity of from 3,000 to 4,000 lbs. of calcium oxid per acre. The nitrogen is either taken up as ammonia or else nitrification proceeds to a considerable extent in the presence of the acid."

The forms of phosphorus in granitic soils, C. VINCENT (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 10, pp. 409-411; abs. in Jour. Soc. Chem. Indus., 36 (1917), No. 8, pp. 465, 466).—It is pointed out that while granitic soils are generally supposed to be poor in phosphoric acid since they respond to phosphatic applications, the application of lime or chalk has a similar effect. This is attributed to the existence of the phosphoric acid in unavailable organic combinations with humus which must be neutralized before the phosphoric acid becomes available.

"If these soils be digested near the boiling point with concentrated nitric acid for four hours, only a portion of the total phosphoric acid is found on analysis, but if the soil be first neutralized with lime, or dried and calcined, before digestion, the whole of the phosphoric acid is obtained; the difference may be very considerable. Under these conditions the granitic soils are found to be moderately rich in phosphoric acid and some of them very rich. In the majority of cases the application of a light dressing of lime, calculated for four to five years, combined if necessary with potash and farmyard manures, will suffice to make the phosphoric acid and a portion of the nitrogen readily available."

Report on availability of potash, E. E. Vanatta (Jour. Assoc. Off. Agr. Chem., 3 (1917), No. 1, pp. 105-107).—Pot experiments with sweet corn conducted at the Missouri Experiment Station are reported in which a mixture of washed quartz sand with sufficient fine ground feldspar to supply 0.66 per cent total potash was used. Sufficient other fertilizer for maximum plant growth was also added. Other individual treatments included the addition of blue grass at the rate of 30,000 lbs. per acre, heating the feldspar to 100° C., and the addition of calcium carbonate at the rate of 4,500 lbs. per acre, of calcium oxid at the rate of 3,000 lbs. per acre, and of starch at the rate of 10,000 lbs. per acre.

It was found that "the addition of a large amount of organic matter in the form of blue grass . . . had a beneficial effect on plant growth, either by furnishing available potash on its decay or by liberating potash from the feldspar. The addition of organic matter in the form of starch . . . retarded plant growth. Calcium carbonate apparently . . . had slight effect on plant growth, while calcium oxid apparently . . . retarded plant growth. The results of this work indicate that the potash compounds in feldspathic rock are of little value in furnishing readily available plant food."

Importance of developing our natural resources of potash, F. W. Brown (U. S. Dept. Agr. Yearbook 1916, pp. 301-310, pl. 1).—This article deals with the natural and artificial potash resources of the United States, including byproducts of cement manufacture, blast-furnace gas, wool and wood wastes, natural lake brines, alunite, and kelp. Processes of extracting potash from these are briefly described.

"At present the Pacific kelps appear to be one of the most hopeful sources of an adequate supply of potash for the country's needs."

Fertilizer experiments with lime on tobacco soils, 1912–13, N. H. COHEN (Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 17 (1915), pp. 5–15).—Fertilizer experiments to determine the influence of liming on the quality, color, and burning qualities of tobacco showed that liming did not increase the tobacco yield but improved its quality and color and the color of the ash. Its burning qualities were injured, however.

Fertilizer experiments with lime on tobacco soils, 1913-14, E. Sidenius (*Proefstat. Vorstenland. Tabak* [Dutch East Indies], Meded. 17 (1915), pp. 19-40).—Experiments on the influence of liming on tobacco soils are reported.

It was found that in some cases the quality of the tobacco was improved and in some cases injured. In the majority of cases the lime was especially active. Liming reduced the percentage of light-colored leaves, but in no case the burning qualities of the tobacco. The color of the ash was improved by liming in some cases, but in most cases no difference was observed between limed and unlimed plats. The results as a whole are taken to indicate that no great profit resulted from the liming of tobacco soils.

Ground limestone for use in New York State, J. F. Barker and W. W. Baer (New York State Sta. Bul. 430 (1917), pp. 21-32, pls. 4, fig. 1).—This gives data on the distribution of limestone production in New York, reports analyses of 69 samples of ground limestone produced by New York plants and by companies in near-by States shipping limestone into New York, and gives general information on the comparative values of ground limestones and on their use in agriculture.

The international trade in fertilizers and chemical products useful to agriculture, P. Van Hissenhoven (Internat. Inst. Agr. Rome, Internat. Crop Rpt. and Agr. Statis., 8 (1917). No. 3, pp. 239–308).—This, the sixth of these semiannual reviews, is dated March, 1917, and gives comparatively complete statistics for 1913 and 1914 and incomplete data for 1915 and 1916. The data are taken from both official and private sources. Generally speaking, the more recent information is largely from private sources, while the official data are, as a rule, not later than 1913 and 1914.

It is stated that the phosphate mined in the United States fell to 1,865,123 metric tons in 1915. The shipment of Florida hard rock was almost insignificant in 1916, namely, 33,000 tons, of which 4,600 tons was for domestic use. The decline in shipment of land pebble was not so great. "In 1916 and in 1915 shipments to countries other than the United States were practically identical in quantity, but they both show a deficiency of nearly 700,000 tons as compared with the shipments of this description of phosphates effected prior to the war." Shortage of labor and of sulphuric acid are named as causes of this decline. The exports of Tunisian phosphate increased in 1916 to 352,000 tons as compared with 226,000 tons in 1915 and 355,000 tons in 1914. There was increased activity in 1916 in exploitation of the Pacific islands phosphates. The exports of Egyptian phosphates declined something over one-third in 1916.

The estimated total production of potash salts in Germany in 1916 is reported to have been 900,000 tons. Of the 24,638 tons of saltpeter produced in India in 1916, 21,749 tons went to Great Britain and Ireland. The average prices per metric ton of the principal potash salts in the United States (New York) during 1916 were as follows: Kainit, \$45.26; sulphate of potash, \$315; and muriate of potash, \$400. The prices for these salts remained fairly constant during the year, being slightly lower on the whole at the end than at the beginning of the year.

The production of nitrate of soda was slightly less during the second half of 1916 than during the first. The stocks on hand on the Chilean coast were not more than 718,315 tons at the close of 1916. The total production for the year was 2,914,542 tons, and the export, 2,991,786. The exports to Europe and Egypt amounted to 957,772 tons during the last half of 1916, as compared with 673,348 tons during the corresponding period of 1915. The exports to the United States during the second half of 1916 amounted to 592,901 tons, as against 452,582 tons in 1915. Of the amount exported to the United States, 526,261 tons went to the Atlantic States and 51,683 tons to the Pacific States. The average price in New York during 1916 was \$72.35 per metric ton.

The statistics for production of sulphate of ammonia during 1916 are very incomplete. The production in Great Britain and Ireland from all sources in that year was 445,029 tons, of which 263,473 tons was exported. The production in the United States was 294,835 tons, as compared with 199.571 tons in 1915. Of this amount, 246,754 tons was obtained from coke ovens and 48,081 tons from gas and carbonizing works. The United States imported 13,170 tons of sulphate of ammonia during the year. The average price of sulphate of ammonia in New York for 1916 was \$83.86 per metric ton. Incomplete statistics show that synthetic nitrogen compounds were exported during the year by Norway to the extent of \$2,276 tons.

As regards fertilizers in general, the statistics since the beginning of the war are very incomplete. In general, an increasing demand prior to the war was evident in Russia, Japan, South Africa, Australia, and Hawaii, with an inadequate supply since that date. Among other products useful to agriculture for which statistics are given are sulphur and copper sulphate.

An extensive bibliography of recent literature on fertilizers and chemical products useful for agriculture is given as usual.

Fertilizer analyses, A. J. Patten, E. F. Berger, A. E. Smoll, and E. A. DeWindt (Michigan Sta. Bul. 278 (1916), pp. 3-31).—This bulletin contains the results of actual and guaranteed analyses of 549 samples of fertilizers and fertilizing materials collected for inspection in Michigan during 1916. It was found that of the 549 samples "30 (5.5 per cent) are below guarantee in nitrogen, 38 (6.9 per cent) are below in available phosphoric acid, 6 (1 per cent) in total phosphoric acid, and 23 (4.2 per cent) in potash."

### AGRICULTURAL BOTANY.

Department of botanical research, D. T. MacDougal (Carnegie Inst. Washington Year Book, 15 (1916), pp. 51-95).—A summary is given of the more important results as condensed from the reports by the several investigators taking part in the various phases of botanical work. The groupings under which the work is reported include photosynthesis, imbibition, and growth; ecology and phytogeography; genetics and taxonomy; eremography; equipment; and field work.

It is stated that the study of the available facts and accepted conclusions regarding photosynthesis eliminates the theory of Baeyer from the possible explanations. The initial stage is probably much more complex than a simple condensation of formaldehyde to sugar. A study of the cacti regarding the carbohydrate economy of plants yields no evidence of special formative substances. Sugar starvation may occur as a result of desiccation or of enzyminhibiting temperatures even when plenty of starch is present.

The lower temperature limit of growth in a single plant may range from 10 to 25° C, and the upper from 26 to 43°, with a maximum of 49° for growth and as high as 53° for endurance. Temperature coefficients of 2 or more for every rise of 10° were found between 10 and 30 or 35°. All temperatures were those of the plant body itself, which may be as much as 8 to 9° above that of the surrounding air.

The precision auxograph now in use indicates reliably an increase or decrease in length or thickness to within 0.0004 in. No inhibiting effect of light on growth of *Eriogonum nudum* was shown, the maximum occurring in daylight and the rate depending largely upon the balance between absorption and water loss. Imbibition, defined as distensive force in the earlier growth of the cell, plays an important but diminishing part as vacuoles form and the protoplast enlarges, osmosis meanwhile increasing in importance. Acidity checks growth, most

plants having a greater capacity for water when slightly alkaline. Water capacity of cacti increases with the dry weight up to the age of one year or more (maturity), then decreases. Gelatin with a little agar makes a mixture displaying imbibition comparable to that of plants. Imbibition capacity (which is less at night than in the daytime) influences transpiration and movements. Studies were made on the relative influences of imbibition and turgor in the growth of pollen tubes in cane sugar, acids, and alkalies. The contained colloids swell more in acid than in alkali of low concentrations.

The ratio of precipitation to evaporation is the factor which limits the areas of forest, grassland, and desert. A new subdivision of vegetational areas has been worked out, as well as a new method of determination of the domination of different growth forms.

Flattened plant bodies meridionally placed receive more heat than those set at right angles to this position, attaining temperatures of 53° C. (127.4° F.) or more and transpiration and dry weight corresponding to the exposure. Roots of different plants show varied relations to oxygen, which is correlated with soil penetration and habit, and similar differences appear as regards the temperature conditioning growth. The forms taken by root systems are greatly affected by environment. Roots of Salix will grow for some time without oxygen.

Extensive study has been made of the concentrations of the sap of plants in mountain and desert habitats. Sap of parasites is usually, but not always or necessarily, of higher concentration than that of their hosts.

Wide divergences appear in the progenies of single species of Enothera from widely separated localities, and striking aberrants or mutants were noted. The revegetation of an island has been followed since 1908, when there were two individuals present, to 1916, when there were 470 individuals, representing 10 species.

Variations in climate as related to vegetation in earlier geological periods are attributed chiefly to the frequency and distribution of cyclonic storms. The study of the Mohave River yields evidence which is of value in making out the evolutionary history of the vegetation in this ancient desert. The underflow being of great importance to vegetation, it has been found that artesian conditions would not necessarily require a bowl-shaped basin, and some generalizations of practical value have been obtained.

Osmotic pressure in roots and in leaves in relation to habitat moisture, V. Iljin, P. Nazarova, and M. Ostrovskaja (Jour. Ecology, 4 (1916), No. 3-4, pp. 160-173).—The authors have made a study of the vegetation (represented by various genera and species) of three types, swamp, meadow, and grass steppe, in the Valuyki district, in the Government of Voronezh. It is stated that the influence of differences in water supply can be noted in leaf and root. The osmotic pressure shows variations due to external influences as well as to internal structure. A close relation is always observable between intensity of osmotic pressure and the amount of water at the disposal of the plant cell.

Nitrogen compounds in mulberry leaves, E. Katayama (Bul. Imp. Sericult. Expt. Sta. Japan, 1 (1916), No. 1, pp. 1-30).—The author reports on a study of the various ditrogen compounds and their percentages present in mulberry leaves, with some reference to their utilization by silkworms in their nutritive processes and in the manufacture of their products.

The emergence of the aerial organs in woodland plants, E. J. Salisbury (Jour. Ecology, 4 (1916), No. 3-4, pp. 121-128, figs. 7).—A study has been made of the three principal types of adaptation to overcome the resistances to emergence from the soil by various plants on germination.

It is considered as an important feature of both spear leaves and spear shoots (in which the leaves are rolled parallel to the midrib) that the unfolding begins at the apex and travels downward, the tip of the leaf or shoot thus developing an increased periphery on reaching the light, while the part below remains small, thus greatly reducing resistance to the emergence of the remaining part of the shoot or leaf. The third (and in some respects more elaborate) type, in which the stem or petiole emerges in a bent condition, is dealt with in some detail. It is stated that the straightening of the bent organs is a growth phenomenon which normally takes place under the stimulus of light at a rate corresponding somewhat to its intensity, but sometimes occurring eventually in darkness.

Linkage in maize: Aleurone and chlorophyll factors, E. W. Lindstbom (Amer. Nat., 51 (1917), No. 604, pp. 225-237).—The author states that linkage between R, one of the aleurone factors (of which there are said to be 5 pairs), and G, one of the chlorophyll factors (of which the author has found that there are at least 7 pairs), shows approximately 20 per cent crossovers, the crossing over occurring in both male and female gametogenesis of the monecious maize plant. Preliminary tests indicate that G is also linked with L, a seedling chlorophyll factor, the factor pairs Rr, Gg, and Ll constituting one factorial group in maize.

The different meanings of the term "factor" as affecting clearness in genetic discussion, H. B. Frost (Amer. Nat., 51 (1917), No. 604, pp. 244-250).— The author proposes to employ in genetic discussion the two distinct meanings now in use for the term factor, so that a genetic (Mendelian) factor will mean, in one sense, a property or characteristic of the germ plasm, more or less conveniently delimited for the analysis of segregating heredity; in the other, an actual material unit of genetic segregation, of unknown nature, but probably a genetically indivisible portion of a chromosome in a particular state. The presence-and-absence scheme employs properly the first only of these meanings; the Morgan-Castle scheme may use either.

Notes on the flora of Sitka, Alaska, J. P. Anderson (*Proc. Iowa Acad. Sci.*, 23 (1916), pp. 427-482, figs. 16).—The author, presenting the results of collections, observations, and research of two years near Sitka, states that in the area in question the Canadian, Hudsonian, and Arctic-Alpine zones are represented. The plants segregate into five or six typical habitats, which are systematically discussed, as are economic plants including forest, fruit bearing, and other species. A number of fungi are listed with their hosts. The collections made are to be added to those at the Alaska Sitka Experiment Station.

An account of the chief types of vegetation in South Africa, with notes on the plant succession, J. W. Bews (Jour. Ecology, 4 (1916), No. 3-4, pp. 129-159, fig. 1).—Giving a somewhat extended, though confessedly incomplete, account of the vegetation prevalent in portions of South Africa as related to various factors, the author states that the types of vegetation found there are very varied, showing many stages and tendencies as regards order of succession. One striking feature is the rarity of formations or associations dominated by a single species. In some cases, but not all, this may be considered to indicate a lack of stability in the environmental conditions.

Experiments on the effects of constituents of solid smelter wastes on barley growth in pot cultures, C. B. Lipman and W. F. Gericke (Univ. Cal. Pubs. Agr. Sci., 1 (1917), No. 13, pp. 495-587).—Following some preliminary investigations by Lipman and Wilson previously noted (E. S. R., 30. p. 130), the present authors institued in 1912 new and more complete experiments to ascertain whether sulphates of such metals as copper, zinc, lead, iron, and manganese in soil are toxic to barley; whether these substances are toxic in the

proportions in which they may be present around smelters; whether they may be carried down to crops by water; whether they may prove to be permanently or temporarily stimulating to plants; and whether potassium aluminum sulphate can possess any value as a stimulant or as a source of potash. This work is herein described and its results are discussed in some detail, and some comparisons are shown with findings of other investigators.

The effect of various concentrations of the several compounds employed in connection with the different soils are indicated in connection with the growth attained by grain, straw, or roots. Stimulation usually attended the use of low and, in some cases, rather high concentrations.

Results are given regarding the effects of the salts on the nitrogen content of the grain, the nitrifying powers of the soil, and the amounts of copper and zinc taken up. Correlations are noted between some of these factors and the yields of dry matter. Some theoretical and practical phases of the smelter question are discussed, and evidence is cited to show that the solids of smelter waste are not a menace to agriculture.

Some effects of salt-treated soils on absorption by seeds, W. F. Gericke (Soil Sci., 3 (1917), No. 3, pp. 271-278).—The work above noted having raised the question whether, owing to absorption, an increase would occur in the weight of good viable seeds planted in soils containing solutions of certain toxic salts, the author has carefully studied the behavior in this respect of the seeds of several common economic plants.

It was found that smaller applications of copper sulphate to soil increased, and larger additions decreased, the absorption of water by bean and barley seeds. Small applications of sodium carbonate to soils increased the weight of bean, barley, and maize through increased absorption. Small applications of sodium chlorid decreased water absorption by all of these seeds.

Certain effects under irrigation of copper compounds upon crops, R. H. Forbes (Univ. Cal. Pubs. Agr. Sci., 1 (1917), No. 12, pp. 395-494, pls. 4, figs. 16).—Investigations are reported which show that as a direct effect of the Clifton-Morenci mining operations in Arizona, copper is distributed throughout the water supplies, soils, and the vegetable and animal life of an underlying irrigated district.

"Smaller amounts of copper are found elsewhere in the State where the drainage basin includes mining operations or ore-bearing areas. Individual plants grown in water cultures or in soil containing copper show a comparatively small, and probably not injurious accumulation of copper in the aerial portions of the plants, but the root systems, carefully cleansed of externally adhering copper, contain relatively great amounts. Copper in root systems, as shown by the biuret test, is largely in combination with plant proteids, especially at the growing points of root systems and near vicinity. . . . Conditions favoring toxicity of copper compounds are the presence of carbon dioxid and certain soluble salts which assist in forming copper solutions that come into contact with plant roots; coarse, sandy soils favoring free access of copper solutions to plant roots and minimizing the withdrawal of copper from solution by adsorption; and the presence of copper in the form of the more soluble precipitated carbonate. . . .

"Conditions opposing toxicity of copper compounds are the presence of copper in the form of chrysocolla and chalcocite; adsorption through contact with finely divided soil particles; reactions with carbonates, silicates, and organic matter tending to precipitate copper from its solutions; the presence of certain soluble salts in the soil that overcome toxic action; and increased resistance of old plant roots. The stimulation by copper of vegetative growth in pot and water

cultures has been observed. Stimulated growth of crops under field conditions is a possibility.

"Pot cultures may be used for comparative determinations of toxic effects upon plants of copper in soils, if conducted under rigidly uniform conditions. The copper content and the physiological response to copper of such material will be much greater than for similar cultures grown under plat or field conditions. Copper injury in field soils containing doubtfully toxic amounts of copper may be diagnosed by a combination of symptoms. Facts which indicate such injury in a soil containing 0.1 per cent of copper (more or less) are yellow tops (for winter grains) in absence of other conditions that cause yellow tops, crinkly root systems (in absence of excessive amounts of alkali salts), and a high copper content in dry matter of root systems. Combined evidence of this character, which may be observed in the district studied, indicates toxic copper effects.

"Field observations before and following the exclusion of tailings from the irrigating water supply indicate that conditions in the district studied are gradually improving, due to the cultivation of alfalfa and to the incorporation of river sediments with accumulations of tailings. Noticeable toxic effects in the field exist only where the roots of young, growing crops are exposed to surface soils containing maximum amounts of copper. The general tendency in the district is probably toward decreasing rather than increasing percentages of copper in irrigated soils."

Methods of experimental procedure are described.

Fifty-seven references to literature bearing on the subject are appended.

Protection against pollution of waters and smoke and dust injury to agriculture and forestry in Austria, J. Stoklasa (Mitt. Verhandl. Landw. Rats [Austria], 17 (1913), pp. 141-163).—Besides discussing reports on emanations from such sources as furnaces and chemical works in different countries during some years past, the author deals more specifically with several phases of water pollution and with such emanations as smoke, dust, and gases, and the injury done thereby to plants.

One of the most important of the injurious factors is sulphuric acid, which is discussed as regards its effects, both direct and indirect. The action on the leaves is far-reaching as regards results, though not necessarily apparent in the early stages of the processes. The effects of some other components are somewhat systematically discussed.

# FIELD CROPS.

Field experiments and compensating calculations, R. Leidner (Landio. Jahrb., 49 (1916), No. 1, pp. 105-135, figs. 3).—The author reviews experimental work by Rümker, Rodewald, Hummel, Remy, Ehrenberg, Pfeiffer, Mitscherlich, and others in an attempt to ascertain those methods that secure the greatest accuracy in field experiments. Considerable data are given and discussed.

The general conclusion is drawn that the most suitable means for conducting field experiments has not yet been found, although the transition from the early two-plat system to the newer method of using many small control plats and the detailed statement of the technical and mathematical phases of the subject studied are advances in the right direction. A more careful selection of experimental field plats and increased attention to all the details of experimental work are natural consequences following such a practice.

[The experimental error in field tests], V. G. Batyrenko (Zhur. Opytn. Agron. (Jour. Agr. Expt.), 17 (1916), No. 2, pp. 99-121).—The author discusses the factors involved in experimental errors in field tests, with special reference

to the influence they may have when the results obtained from plat tests are applied to open field practices. Two types of plat experiments are considered, those for testing methods and those for testing yields.

[Report of field crops work], W. G. TAGGART, A. P. KERR, C. E. HESTER, and F. C. QUEREAU (Louisiana Stas. Rpt. 1916, pp. 7-9, 24, 25, 26-29).—This continues work previously noted (E. S. R., 35, p. 336).

Fertilizer experiments with sugar cane at the Sugar Experiment Station showed an average increase of 3.03 tons of cane from sulphate of potash applied to first-year stubble, thus confirming results obtained the year before with plant cane but contradicting many experiments of previous years. An application of 500 lbs. each of acid phosphate and tankage on second-year stubble showed an increased production over an application of 250 lbs. of acid phosphate and 500 lbs. of tankage which a little more than paid for the extra amount of fertilizer. The failure of this experiment to yield tonnage equal to that obtained the past four years is attributed to a disturbance of the nitrogen balance by continuous cropping to sugar cane.

Four foreign varieties of sugar cane were tested. Louisiana seedlings L511 and L231 continued to maintain their high standard.

Attempts to develop a white flint corn were continued and a yield of 63 bu. per acre obtained in spite of injury by heavy winds. So-called prolific varieties of corn recommended by other southern experiment stations in the same latitude were obtained and grown in comparison with native Yellow Creole, but none gave superior yields.

In an attempt to increase the value of hay grown on Johnson grass infested land, two cuttings of clean red clover were secured before the Johnson grass got any headway. The early growing period of the clover, however, prevented the cutting of a mixed Johnson grass and clover hay. Further observations on the eradication of Johnson grass by kudzu were made and indicated that this plant will completely choke out the grass in a very few years.

In fertilizer experiments with rice at the Rice Experiment Station conducted since 1910 five profitable crops of rice have been grown on all plats receiving available phosphorus, the highest yield being 28 bbls. per acre. The last two crops, however, yielded less than the checks, due to the heavy growth of water crab grass and barnyard millet. Potash showed profitable yields the first year, but subsequently the yield has been little more than on the check. Cottonseed meal or manure appears to be profitable when applied to Honduras rice, but the increase was not so marked with Shinriki or Blue Rose rice.

Field tests are briefly noted with green mungo beans, the Biloxy soy bean, velvet beans, garlic, clovers, Japanese cane, teosinte, sorghum, and peas for silage, Sudan grass, corn, and oats.

Dry farming investigations at the Sherman County branch experiment station, Moro, Oreg., D. E. Stephens and C. E. Hill (Oregon Sta. Bul. 144 (1917), pp. 3-47, figs. 13).—Variety, crop improvement, and rotation tests and tillage experiments to determine the best cultural methods for wheat production under the summer-fallow system are reported. The tests were made at the Moro substation in eastern Oregon and were conducted in cooperation with the Office of Forage Crop Investigations of the U. S. Department of Agriculture. The history of the branch station, meteorological data, and a report of variety tests of spring cereals have been previously noted (E. S. R., 36, p. 830).

Four-year average yields of 17 winter wheat varieties show the Argentine (1569) to be first, with 32 bu. per acre, while Ghirka (1438) was last with 24.6 bu. The local Turkey variety commonly grown in the vicinity of Moro and

taken as a standard, yielded 27 bu. per acre. The first 9 varieties—all wheats of the Turkey type, exceeded the local Turkey strain by from 6 to 18 per cent. The highest yielding Turkey variety exceeded Fortyfold, a popular variety in eastern Oregon, by 6.6 bu. per acre. Hybrid No. 123 yielded 43.8 bu. for a 2-year average.

Rate- and date-of-seeding tests with winter wheat indicate that from 45 to 55 lbs. of seed per acre, sown between October 10 and 25, will give best results.

A comparison of Turkey wheat grown from seed produced at Moro and Moccasin, Mont., and Nephi, Utah, gave 5-year average yields of 30.1, 30, and 28.1 bu. per acre, respectively.

In variety tests with spring wheats, using Bluestem as a standard, Koola, a pure-line selection, gave the highest average yield, 32 bu., for the 4 years 1913–1916, while Kubanka gave the lowest average yield, 21.2 bu. Bluestem yielded 25.4 bu.

Rate- and date-of-seeding tests with spring wheat gave a 5-year average yield of 17.7 bu. per acre for all rates sown early (March 28), while the late sowings (April 23) averaged 12.2 bu. per acre. The 8-pk. rate of seeding gave the highest average yield, 20.3 bu., for the early sowings, while the 3-pk. rate gave the highest yield, 13.6 bu., for late sowing.

Texas Winter barley gave the highest average yield of the 5 varieties tested, 49 bu., and Utah Winter the lowest, 36.8 bu. per acre. None of the beardless varieties tested have been winter hardy.

Of the 24 spring barleys tested for 4 years, Mariout has given the highest average yield of 51.6 bu., with White Smyrna second, with 50.1 bu. per acre. Manchuria gave the lowest average yield of 31.7 bu.

The highest 4-year average yield of spring oats was secured from Siberian and amounted to 62.1 bu., while Canadian was lowest with 52.3 bu. per acre. In seasons of normal or less than normal rainfall early-maturing varieties such as Sixty Day and Kherson gave the highest yields, while in cool seasons of high rainfall the late-maturing varieties gave considerably higher yields. The earlier varieties are recommended, however. Winter oats have not proved hardy.

The leading varieties of the cercals named above are briefly described.

In a comparison of emmer and spelt varieties tested for the 3-year period of 1914–1916, Red Winter spelt gave an average yield of 57.4 bu. as compared with a yield of 29.4 bu. from Black Winter emmer No. 2337, the highest-yielding emmer variety.

Abruzzes and Giant Winter ryes have given the highest yields of the winter types tested, while a spring rye, No. 26101, has proved exceptionally valuable.

Tabulated data are presented showing the acre value of the grain crops based on the highest-yielding varieties of winter and spring wheat and barley, spring oats, and winter spelt, and on 10-year average prices. Mariout spring barley, with an average yield of 2.477 lbs. per acre. gave the highest acre value, \$33.06, and Red Winter spelt, with a yield of 1,837 lbs., the lowest, \$24.52.

Field peas have proved to be the most profitable of all leguminous crops tested. The Lima variety gave the highest average yield in variety tests extending over the 4-year period of 1913–1916, yielding 22.8 bu. per acre, while White Scimitar was lowest with 14.9 bu. A few of the leading varieties are briefly described.

An average yield of 18.8 bu. per acre was obtained from field peas grown continuously on the same land without summer fallow from 1912 to 1916, inclusive. Field peas substituted for one summer fallow in a 4-course rotation

of fallow, spring wheat, field peas, and spring wheat yielded 15.7 bu. per acre. Wheat after peas yielded 22.3 bu. and after fallow 23.5 bu. New field-pea and wheat rotations begun in 1916 on land sown to field peas continuously since 1912 gave average yields of 40.2 bu. of spring wheat after field peas, 27.4 bu. of field peas after field peas, and 38.5 bu. of wheat after summer fallow.

An attempt was made to determine the relative amounts of soil moisture used by field peas, wheat, and corn, as compared with the amount conserved by summer fallowing. The following average results were secured from two determinations: After spring wheat yielding 39.4 bu., 7.5 per cent moisture; after corn yielding 27.1 bu., 8 per cent; after field peas yielding 27.7 bu., 9 per cent; and after fallow, 13.4 per cent.

Numerous alfalfa varieties have been tested and produced excellent yields of forage but, with the exception of Baltic and Grimm, have failed to produce seed. Results obtained with sweet clover indicate that it may be equal to or even superior to alfalfa as a hay crop. Several varieties of vetch have been tested, with the best results being secured from fall-sown hairy vetch.

In variety tests with corn Northwestern Dent, with a 4-year average yield of 23.2 bu. per acre, was highest and Minnesota No. 23 lowest with 14.4 bu. Walla Walla White Dent and Minnesota No. 13, with average yields of 22.5 and 19 bu., respectively, are especially recommended for silage purposes.

Green Mountain, with a 4-year average yield of 184 bu. per acre, was first in potato variety tests, with Early Ohio lowest with 100.2 bu. Early Rose, Burbank, and Irish Cobbler gave average yields of 155.5, 150.3, and 141.8 bu., respectively.

In the tillage experiments, tests of methods for disposing of the wheat stubble resulted as follows:

Effects of various treatments of the stubble on the yield of winter wheat grown after fallow, 1913-1916, inclusive.

Date of plowing.	Diskedin fall and spring.	Disked in spring only.	Not disked.
April 1. May 1. June 1	Eushels. 26.6 27.2 27.2	Bushels. 29, 9 29, 0 25, 9	Bushels, 33.5 27.2 21.0

Tests of the time and manner of plowing for winter and spring wheat showed an average yield of 28 bu. per acre for early fall plowing, as compared with 25 bu. for late fall plowing and 29.9 bu. for early spring plowing (April 1). Disk plowing gave an average yield of 25.7 bu., while moldboard plowing averaged 27.2 bu. In early fall plowing with a disk plow the average yield amounted to 26.5 bu. and with the moldboard plow to 29.2 bu., while in late fall plowing the difference was negligible. The 4-year average yield of winter wheat on plats plowed April 1 amounted to 7.8 bu. per acre more than the average yields of plats plowed June 1, although these variations are said to be largely dependent upon seasonal conditions. Spring wheat sown on plats plowed deep yielded 19.1 bu. and on plats plowed shallow 18.7 bu. per acre.

Analyses of samples of wheat grown on land plowed April 1 and June 1 showed a marked increase in yellow-berry on the late-plowed land, amounting to almost 84 per cent in 1915. The protein content of the kernel on the early and late plowed lands amounted to 13.35 and 8.49 per cent, respectively. The moist gluten content with early plowing amounted to 30.4 per cent and after late plowing to 18.7 per cent.

Winter wheat grown after a fallow and on land packed with a subsurface packer gave a 4-year average yield of 26.2 bu., as compared with 26.8 bu. from land not packed. The average yield from land packed by the surface packer was 26.4 bu. Spring wheat after a fallow yielded an average of 20.1 bu. when packed with the subsurface packer and 20 bu. per acre when not packed.

In a comparison of no harrowing, light harrowing, and heavy harrowing and weeding of the summer fallow for winter wheat, 4-year average yields for three plowing dates April 1, May 1, and June 1 amounted to 24.2, 26.6, and 27.2 bu., respectively. There was little difference between the treatments for any but the earliest plowing date (April 1), when average yields of 25.6, 30.2, and 33.5 bu., respectively, were secured.

The average yield of winter wheat on plats harrowed in the spring amounted to 26.4 bu., as compared with 27.4 bu. from plats not harrowed, thus indicating that except for weed eradication spring harrowing of winter wheat is not necessary or desirable.

Considerable tabulated data are presented and discussed, summarizing the results obtained in rotation experiments with spring and winter wheat, spring barley, spring oats, corn, field peas, and potatoes for the period of 1913–1916. The results, however, are not considered conclusive.

Progress report, Substation No. 4, Beaumont, Tex., 1909-1914, H. H. LAUDE (Texas Sta. Bul. 200 (1916), pp. 3-18, figs. 4).—The history and development of this substation are briefly outlined and the work and results obtained from its establishment through the crop season of 1914 are discussed. The substation is located on a so-called "old rice field" at an elevation of from 26.5 to 29.8 ft. above sea level, near the southeastern corner of the State. Red rice, weeds, and grass common to old rice fields were present, and the whole farm was characterized by the poor drainage facilities which predominate on most of the rice farms of the region. The rainfall is well distributed throughout the year and totals approximately 45.09 in.

Experimental work has dealt largely with rice and a study of the practices related to rice farming, including cultural methods and variety and rotation tests. In date-of-seeding trials the average yields for 1913 and 1914 varied from 270 lbs. per acre for seedings made March 24 to 1,660 lbs. for seedings made June 3. Rate-of-seeding tests conducted during 1913 and 1914, employing 60-, 80-, and 100-lb. rates per acre, resulted in average yields of 1,270, 1,260, and 1,525 lbs. per acre, respectively. A comparison of broadcasting with drilling in rice on dry land in 1913 resulted in yields of 927 lbs. per acre with the former method and 1,930 lbs. with the latter.

The yields of rice obtained in 1914 on plats sown to various other crops in 1913 are reported in tabular form. The highest yield of rice, amounting to 1,911 lbs. per acre, was secured after cotton, while the lowest yield, 1,068 lbs., was obtained after rice. The legumes (cowpeas, peanuts, sweet clover, and soy beans) also proved beneficial to the succeeding rice crop, giving yields ranging from 1,721 lbs. after soy beans to 1,774 lbs. after cowpeas. Rice after fallow yielded 1,412 lbs.

Rod-row tests have been conducted with 122 varieties of rice and 3-year average yields of 18 of these varieties are reported in tabular form. The average yields reported varied from 3.23 lbs. per nursery row for the Chien-Yu variety to 1,603 lbs. for the Honduras variety.

Methods for the control of red rice, grass, and weeds are suggested.

Hay crops have not proved very satisfactory, due to the high humidity prevailing at harvest time. Sudan grass yielded 2.48 tons of cured hay per acre from a 15-lb. rate of seeding in 1914, but suffered a large percentage of loss. Japanese sugar cane (E. S. R., 37, p. 140) is considered the best forage crop

grown at the station, producing as high as 24 tons of green forage per acre. A rate-of-seeding test with Japanese sugar cane in 1914, using rates of approximately 800, 2,000, and 4,000 lbs. of cane, gave yields estimated at 19,226, 27,687, and 36,524 lbs. per acre, respectively.

An experimental planting of Bermuda grass, burr clover, and Lespedeza is reported to have given good results in a test of pasture mixtures begun in 1911 and 1912.

[Field crops], C. A. Zavitz (Ann. Rpt. Ontario Agr. and Expt. Union, 37 (1915), pp. 12-38).—This is a report of cooperative field experiments in Ontario with different varieties of grain crops, roots, forage and silage crops, and fertilizer tests with potatoes, mangels, and rape for the year 1915.

Cultivated plants. Potatoes and sugar beets, H. HITER (Plantes Sarclées. Pomme de Terre et Betterave. Paris: J. B. Baillière & Sons, 1916, pp. 498, figs. 26).—This work is presented in two sections, one dealing with potatoes and the other with sugar beets, each crop being discussed in considerable detail.

Contribution to the study of Gramineæ, C. D. GIROLA (Bol. Min. Agr. [Argentina], 19 (1915), No. 10-12, pp. 867-874, fig. 1).—Some notes are given on Sporobolus phleoides, including chemical and physical analyses.

The relation of winter temperature to the distribution of winter and spring grains in the United States, S. C. Salmon (Jour. Amer. Soc. Agron., 9 (1917), No. 1, pp. 21-24, figs. 2).—This paper discusses some studies begun during the winter of 1913-14, at the Kansas Experiment Station, to determine the relation between winter temperatures and the distribution of winter and spring grain in the United States. The data have been collected from the Census reports and Weather Bureau records of the United States and Canada. Two outline maps of the United States and Canada, upon which isotherms have been plotted, illustrate the distribution of winter and spring wheat. The isotherms connect points of equal daily minimum temperature for January and February.

The isotherm of 10° F. coincides with the line which divides the winter from the spring wheat belt. Practically the only exception is where spring wheat is grown south of the isotherm, rather than where winter wheat is produced north of it.

The isotherms of 20 and 30° coincide very closely with the northern limits for winter barley and winter oats, respectively, agreeing with the statements of Derr (E. S. R., 28, p. 432), Stephens (E. S. R., 32, p. 730), and Warburton (E. S. R., 25, p. 133).

The absence of any correlation between the northern limit of winter cereal culture and snowfall is noted, and may be due to the fact that heavy spring snows, increasing the moisture content of the soil, increase the danger from heaving, thus offsetting the protection afforded by earlier snows.

The effect of greenhouse temperatures on the growth of small grains, T. B. Hutcheson and K. E. Quantz (Jour. Amer. Soc. Agron., 9 (1917), No. 1, pp. 17-21, pls. 2, figs. 1).—This paper reports the results of an experiment conducted by the authors during the winter of 1915, at the Virginia Agricultural Experiment Station, to test the effect of temperature upon winter wheat, oats, barley, and rye grown in greenhouses. The greenhouses were kept as near the following temperatures as outside influences would permit: House No. 1, 75° F.; house No. 2, 65°; house No. 3. 62°; and house No. 4, 58°. The seeds were sown in 4-in. earthen pots on December 21, 1915, and the experiment discontinued May 27, 1916. The results of the experiments showed the effects of temperature to be as follows:

Except in the case of oats, the cool temperature produced earlier maturity, while high temperatures stimulated rank growth of tillers and thus wasted

energy needed for the formation of heads. Barley was affected by heat, while wheat and rye suffered, though not as much as barley. Oats showed very little ill effect from high temperatures, indicating that they are better suited for soil work in greenhouses where temperatures can not be accurately controlled. The setting of seed was best in the cooler houses, although with oats there was apparently no difference in this respect. Tillering was greatest in the warmer temperatures and least in the cooler houses, but the difference in the number of heads was overcome by the large percentage of seed produced per head, except with oats. A temperature ranging from 55 to 70° is deemed most desirable for growing grain in the greenhouse.

Experiments with spring wheat and oats, P. R. Fedorov (Fedoroff) (Bezenchuk, Selsk, Khoz. Opytn. Sta., No. 71 (1916), pp. 14).—Field experiments are reported with spring wheat and oats for 1915. The plan of the experiments included a study of the influence of the preceding crop, plowing at different depths and at different times, fertilizers, various methods of sowing, and seed selection tests. The crops were grown after wheat, peas, corn, sunflowers, millet, potatoes, and carrots.

The best results were obtained from the crops following carrots and potatoes. Late, shallow plowing for wheat appeared to increase yields slightly, but no very definite results were obtained with oats. Mineral fertilizers, consisting of acid phosphates and Thomas slag, showed no increased yields with wheat, but a slight increase with oats. Manure showed good results for both crops.

Broadcasting the seed gave better results than any of the other methods tested. Thrashing injuries of wheat and rye and their influence on the germination and keeping qualities of the grain, J. N. Walldén (Sveriges Utsädesför. Tidskr., 26 (1916), No. 1, pp. 24-47, pl. 1, flg. 1).—This article deals with experiments by the author to determine the extent of injuries to wheat and rye during thrashing and the resultant effect of subsequent copper sulphate treatment on the germination of the seed. A study is also made of the effect of such injuries on the keeping qualities of the grain.

A 0.4 per cent aqueous solution of eosin was used to determine the location and extent of the injury, the seeds being dipped in the solution for one minute, removed and washed with water. The injured portions stained red, while the remaining surface was practically uncolored. The author considered any injury unimportant except such as occurred directly over the embryo. The following gradations are suggested as an indication of the probable degree of injury to the embryo: (1) No color, or only a perceptible tinge, (2) only the apex above the embryo strongly colored, (3) at least one-helf (usually the lower half) of the embryo surface strongly colored, and (4) the entire embryo surface strongly colored. It is claimed that this method will enable one to control the thrashing of wheat and rye when there is risk of injury to the seed.

The keeping qualities of both wheat and rye, but especially the latter, were reduced by injury to the seed coat. Rye showed a marked reduction in its germinability after two weeks, corresponding to the degree of injury sustained.

Further tests showed that in the case of seed with uninjured integument copper sulphate solutions of the highest concentration could be used without subsequent damage to the germinability of the seed, but that a 0.2 to 0.3 per cent formaldehyde solution materially reduced the germinability of such seed. The use of 0.1 to 0.2 per cent formalin, however, had no injurious effect.

The data are presented in tabular form.

Fibres from the Belgian Congo (Bul. Imp. Inst. [So. Kensington], 14 (1916), No. 3, pp. 385-388).—Brief notes are given on fibers received for analysis from the Belgian Congo. The materials comprised baobab bark (Adansonia digitata),

punga bark (*Cephalonema polyandrum*), and several Agave and Furcræa fibers. Both the baobab and punga barks are reported as being suitable for paper making.

535

The agave fibers of Tunis, L. GUILLOCHON (Vie Agr. et Rurale, 6 (1916), No. 52, pp. 458-461, figs. 4).—This is a general discussion of the production of agave fiber in Tunis, with special reference to sisal.

Alfalfa culture, C. G. Williams (Mo. Bul. Ohio Sta., 2 (1917), No. 6,  $p_{\tilde{t}}$ . 173–177,  $g_{\tilde{t}}$ 8. 2).—The essentials in growing alfalfa the first year are enumerated and briefly discussed.

An increased yield of more than 1,200 lbs. of hay per acre for the first year is reported from a 320-lb. application of acid phosphate at Wooster.

Comparative tests with different amounts of seed sown broadcast for three years gave the highest average yield, 9,148 lbs. per acre, with a 10-lb. rate. Further tests using the same rates but comparing broadcasting with drilling in the seed are reported for 1913 and 1914. The highest average yield, 9,569 lbs., was obtained from the 5-lb. rate drilled in, with a 10-lb. rate broadcasted second, with a yield of 9,216 lbs. Counts of the original plants showed 75 per cent remaining after two years from the 10-lb. rate, but only 23 per cent from the 25-lb. rate.

Tests with clipping alfalfa in 1907 indicated that a growth of from 12 to 18 in. might remain without cutting in the fall with no harmful effect to new seedings. Clippings made in September and October of that year were estimated to have reduced the yield from 500 to 1,300 lbs. per acre the following year, and to have increased the percentage of weeds. Clipping in August may be admissible if weeds are serious.

Cassava as a competitor of maize and potatoes in the production of starch and allied products (*Queensland Agr. Jour.*, n. ser., 6 (1916), No. 5, pp. 313-317, ftgs. 3).—This is a general discussion of cassava growing and its substitution for corn and potatoes as a source of starch.

The relation between the anatomical structure and some peculiarities of the different varieties of clover, V. Zholtkevich (W. Joltkewitch) (Zhur. Opytn. Agron. (Jour. Agr. Expt.), 17 (1916), No. 3, pp. 239–250, figs. 3).—The author presents data obtained from two years' observations on the flowering habits and certain anatomical measurements of several varieties of clover. A definite relationship was found to exist between the flowering habits and the length of the cells of the stomata, the diameter of the palisade cells, the internodal length of the stems, and the length of the corolla tube of the different varieties.

Corn culture, T. B. Hutcheson, E. R. Hodgson, and T. K. Wolfe (Virginia Sta. Bul. 214 (1917), pp. 3-12, figs. 2).—A brief review of experimental work conducted in various sections of the country, relative to the value of cultivation for corn, is given, and results obtained at the Virginia Station in similar experiments are reported for 1913–1916, with averages as follows:

Average results of corn-cultivation tests, 1913-1916.

Year.	No cultivation.							
	Weeds allowed to grow.		Weeds cut with		Three cultivations.		Five cultivations.	
	Grain.	Fodder.	Grain.	Fodder.	Grain.	Fodder.	Grain.	Fodder.
1913 1914 1915 1916	Bushels. 7.49 No test. 2.84 14.18	Tons. 0.65 0.45 1.02	Bushels. 27, 81 64, 50 38, 26 65, 59	Tons. 0.88 1.74 1.20 1.83	Bushels. 34, 99 75, 70 51, 51 75, 53	Tons. 1.14 1.77 1.40 2.07	Bushels. 40. 56 73. 10 53. 56 67. 50	Tons. 1.29 1.92 1.26 1.76
Average	8. 17	0.71	49.04	1.41	59.43	1.59	58.68	1.56

An average increase of 40.87 bu. per acre was thus obtained by removing the weeds without any cultivation. Valuing corn at 50 cts. a bushel, the estimated damage sustained by an acre of corn from weeds alone amounted to \$20.44.

Data showing the rainfall during the growing season for each year of the test failed to establish any significant relationship between rainfall and the amount of cultivation necessary.

Recommendations regarding cultivation, the choice of varieties, and the fertilization of the corn crop are discussed in a general manner.

Corn variety tests, 1915 and 1916, L. W. Osborn (Arkansas Sta. Bul. 130 (1917), pp. 3-31).—Corn variety tests at Fayetteville and at the Mena and Marianna substations, and numerous cooperative tests in different parts of the State during 1915 and 1916 are reported, preliminary to a more complete report of all corn experiments since 1903. The results of the tests of each year at each experimental center are tabulated and briefly discussed.

The moisture supply appears to be the limiting factor in corn production, the relative standing of the varieties being closely related to their time of maturity. Early and medium maturing varieties have led in practically all tests, unless seasonal and soil conditions were exceptionally favorable.

A study of the data relative to barren stalks indicates a close correlation between moisture supply, as determined by the character of the soil and season, and the percentage of such stalks produced. Early and medium varieties, as well as the more prolific sorts, showed the lowest number of barren stalks. Surcropper, Hickory King, Biggs Seven-ear, Southern Beauty, Neal Paymaster, Pool Prolific, White Wonder, Leaming. Reid Yellow Dent, and Diamond Joe have contained a minimum of barren stalks in three or more tests.

Hybrids of Zea ramosa and Z. tunicata, G. N. Collins (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 11, pp. 383-396, pls. 9).—Z. tunicata and Z. ramosa are described, the nature of their variations from normal maize outlined, and a hybrid strain secured from a cross of the two made at Lanham, Md., in 1914 discussed in detail. The female parent was a plant of Z. ramosa, while the male was a tunicate strain designated as half tunicate.

Nine  $F_1$  plants of this cross were grown at Chula Vista, Cal., in 1915, of which 4 were tunicate and 5 normal, indicating the heterozygous nature of the half tunicate parent. The tunicate plants were all half tunicate and no trace of ramosa characters were discernible.

F<sub>2</sub> plants were grown at Lanham in 1916 from 3 tunicate and 2 normal ears. The 3 tunicate ears produced 326 mature plants and the 2 normal ears 82 plants. The F<sub>2</sub> progeny of the nontunicate or normal F<sub>1</sub> plants showed segregation into normal and Z. ramosa types in the ratio of 3:1, the numbers being 65 normal and 17 ramosa. No evidence of tunicate characters was observed.

The progeny of the tunicate plants, however, presented many intermediates which have been divided into groups and discussed in detail.

The author concludes that Z. ramosa and Z. tunicata should be regarded as mutative reversions, the one recessive and the other dominant, as compared with normal maize. The hybrid demonstrated that both behave as independent Mendelian units. The  $F_1$  progeny was composed of normal maize, showing none of the characters of either mutation, the recurrence of both parental types in an apparently pure form, and individuals combining the characters of both mutants. In the last group normal expression was inhibited, resulting frequently in the appearance of a totally different type of inflorescence, which was sterile and abnormal to the extent that the tissue remained in an embryonic state, appearing as a much-branched, white, succulent mass, similar to that described by

Blaringhem (E. S. R., 19, p. 1128) and termed by him "cauliflower" inflorescence.

A method for determining the percentage of self-pollination in maize, A. E. Waller (Jour. Amer. Soc. Agron., 9 (1917), No. 1, pp. 35-37).—This paper reports an attempt to determine the percentage of selfing in corn. The test was conducted by the author at the Ohio State University, using Reid Yellow Dent and Wing Hundred-Day White. The hills containing the white corn were spaced a distance of 38½ ft. from hill to hill east and west, and 35 ft. from hill to hill north and south. At the time of tasseling two of the three plants in each hill of white corn were detasseled.

Only one pair of endosperm characters were contrasted, the white and yellow. In endosperm formation in maize, the second nucleus from the pollen fuses with the two polar nuclei in triple fusion. If the male nucleus is the bearer of determiners for a dominant character expressing itself in the endosperm, the phenomenon called xenia then results. The author presents the analysis of 38 ears of white corn, showing the number of yellow (cross-pollinated) and of white (selfed) kernels, with the percentage of selfed kernels.

The average amount of self-pollination obtained was 5.13 per cent, although under field conditions such factors as humidity and wind determine the zone of infection between hills. The author believes that the effect of xenia can be better illustrated by contrasting more than one pair of characters.

Danthonia in New Zealand, A. H. Cockayne (Jour. Agr. [New Zeal.], 13 (1916), No. 5, pp. 352-355, figs. 2).—The two "composite" species of Danthonia used in New Zealand pasture formation, D. semiannularis and D. pilosa, are described and compared. Brief cultural notes are given.

The dasheen; its uses and culture, R. A. Young (U. S. Dept. Agr. Yearbook 1916, pp. 199-208, pls. 6).—The production and uses of the dasheen, with special reference to its place in the agriculture of the Southern States, are discussed, and the origin and the introduction of the crop into the United States briefly outlined.

Flax growing experiments, 1914 and 1915 (Dept. Agr. and Tech. Instr. Ireland Jour., 17 (1916), No. 1, pp. 3-19).—This is a continuation of work previously noted (E. S. R., 32, p. 136), reporting results for 1914 and 1915, which are, in a large part, confirmatory of previous results.

Notes on the cultivation of flax by the ancient Egyptians, H. Munier (Bul. Union Agr. Égypte, 14 (1916), No. 114, pp. 22-26).—This is a brief historical note on the cultivation of flax in ancient Egypt.

Influence of methods of sowing oats on crop yield, M. Archangelskij (Zeml. Ghaz., No. 12 (1916), pp. 313-318; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, p. 826).—This reports the results of field experiments with oats conducted at Tambov in 1914, comparing broadcasting, sowing in rows in the ordinary way, and sowing in sets of rows alternating with bare strips varying in width up to about 12 in. The quantity of seed sown ranged from 0.6 to 1.41 cwt. per acre (2 to 4 bu.). Moisture determinations were made during the summer to a depth of 3 ft., in order to ascertain how the various methods influenced the moisture content of the soil.

With equal quantities of seed, the ordinary method of sowing in rows gave the largest yield and broadcasting the smallest. Increases in the quantity of seed sown influenced the yield, the maximum being attained with 1.41 cwt. sown in ordinary rows. Periodic, superficial plowing of the bare strips showed the greatest conservation of soil moisture and increased the yield.

Percentage of husk in varieties of oats, J. T. PRIDHAM (Agr. Gaz. N. S. Wales, 27 (1916), No. 9, pp. 625, 626).—A number of standard oat varieties and

hybrids were grown at the Glen Innes Experiment Farm for the years 1912, 1913, 1914, and 1915, and 100 uniform grains of each variety selected each year, carefully husked, the kernels and husks weighed, and the percentage of husks determined. Tartar King with 39.94 per cent and Sunrise with 26.31 per cent husks represented the extreme limits in the results obtained.

Standardization and group classification of potato varieties for Michigan, C. W. Waid (Mich. Agr. Col., Ext. Div. Bul. 5 (1916), pp. 15, figs. 8).—A group classification and description of potato varieties best suited to Michigan conditions, based on the classification given by Stuart (E. S. R., 32, p. 830).

[Potatoes], A. Cadoret (Prog. Agr. et Vit. (Ed. l'Est-Centre), 37 (1916), No. 15, pp. 355, 356; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, p. 828).—After a brief review of various methods for a more economical use of seed potatoes, the author describes his own method, which has given good results for several years. The tubers are placed in a dry cellar at a temperature above 17° C. (62.6° F.), and before they wrinkle rooting sprouts are obtained. These sprouts are planted at distances of 8 by 20 in. at a depth of from 2½ to 3½ in., according to the soil. The author states that a crop of 8½ tons (approximately 280 bu.) per acre of marketable potatoes may be obtained. The method is applicable to all loose, light, and relatively dry soils.

The production of potatoes by cuttings, A. Cadobet (*Prog. Agr. et Vit.* (*Ed. l'Est-Centre*), 38 (1917), No. 14, pp. 325-327).—An economic discussion of the above, emphasizing the saving in seed made possible by this scheme. It is estimated that from 595 to 800 kg. of seed per hectare (8.8 to 11.8 bu. per acre) would suffice as compared with 3,333 kg. of seed required by the Girard method (E. S. R.; 5, p. 117).

Potato growing and potato diseases from Maine to California, W. J. Morse (Maine Sta. Doc. 531 (1916), pp. 20).—This is a partial report of the author's observations on a tour of inspection through the leading potato-growing sections of the Northern and Western States in 1914, in company with Appel et al., in order to secure first-hand information on the growing of potatoes and on potato diseases under a variety of conditions. It was presented at the annual meeting of the Maine Seed Improvement Association at Lewiston in December, 1915.

Spraying potatoes in 1916 (Maine Sta. Doc. 522 (1916), pp. 12, fig. 1).—A popular discussion of potato spraying for the control of disease and insect enemies under the market conditions of spray materials then existing.

The transplanting of rice in Egypt, V. Mosséri (Bul. Union Agr. Égypte, 14 (1916), No. 114, pp. 5-13).—This is a preliminary note on two experiments to determine the comparative value of seeding rice in the field and transplanting it from a seed bed. A comparison was also made of early and late seeding and early and late transplanting.

It was found that the cost of production was slightly greater when the rice was transplanted, and the yield considerably less than where the seed was sown in the field, resulting in a net return decidedly in favor of the latter system of cultivation. Early seeding and early transplanting gave larger net returns than late seeding and late transplanting.

Studies in rice, J. C. Rundles (Philippine Jour. Sci., Sect. C, 10 (1915), No. 6, pp. 351-378, pls. 5).—Rice seed selection is discussed in detail, with emphasis on the methods of selection and the factors which should govern the selection of standard varieties, such as production, market demand, maturity, character of the plants, and character of the paddy. Rice growing is discussed in some detail with special reference to the preparation, seeding, and care of the nursery seed bed.

The growing of cultivated leguminous catch crops on the paddy fields during the dry season is recommended, such crops as the peanut, mungo bean, cowpea, and sitao being deemed most suitable for this purpose.

The production of upland rice is briefly discussed.

[Rice improvement], B. MARCARELLI (Gior. Risicolt., 6 (1916), No. 16, pp. 253-257).—This is a general discussion of rice improvement through seed selection.

The nitrogen fertilization of rice, N. Novelli (Gior. Risicolt., 6 (1916), No. 10, pp. 161-164).—This is a brief general discussion of the fertilization of rice with ammonium sulphate, sodium nitrate, and calcium cyanamid.

A remarkable cultural variety of rye in the upper valley of Dora Riparia, Italy, C. F. CERRIANA (Coltivatore, 62 (1916), No. 12, pp. 358-362, figs. 2; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, pp. 825, 826).—This describes a variety of rye grown in certain mountain regions of Italy, and partially adapted to growing in the lower plains region.

The variety is described as differing from common rye in that the culms are shorter, leaves darker and wider, ears denser, grains larger and greenish in color even when fully ripe, yields of grain higher (approximately 27 bu. per acre), and flour whiter, yielding a whiter loaf. This rye tillers freely and, owing to the climatic conditions of the region, is often on the ground from 12 to 13 months. It is especially suited to poor, dry, and wind-exposed soils, and, in combination with common rye, is suitable for fertile soils, provided they are not exposed to excessive humidity or fog. The characteristic qualities of this variety disappear after the second reproduction outside of its natural environment, necessitating a renewal of the seed every three years.

The composition of grain sorghum kernels, J. A. Le Clerc and L. H. Bailey (Jour. Amer. Soc. Agron., 9 (1917), No. 1, pp. 1-16).—This paper gives the minimum and maximum results obtained, and the average composition found, in analyses of several hundred samples of grain sorghums grown at Amarillo, Tex., from 1908 to 1912, inclusive. The results are presented in tabular form and discussed so as to bring out the correlations between the percentage of protein and the weight per 1,000 kernels, and also to show how the composition of grain varies with a high and low protein content, a high and low weight per 1,000 kernels, and a high and low ash content. Data are given on the rainfall at various periods during the growth of different grain sorghums at Amarillo, annually from 1908 to 1912, in an effort to correlate protein content and yield with rainfall.

The competition of the grain sorghums is compared in tabular form with that of many of the other grains and seeds to ascertain their comparative food value.

Analyses are also given of shallu and broom corn, and of bread made in part from grain sorghum meal. This meal is reported as producing a pleasing loaf.

The authors conclude that in the grain sorghums low protein is correlated with high weight per bushel, low fiber, low ash, and low pentosans, and, except in the case of milos, with low weight per 1,000 kernels, although this last is not a definite relationship. From the data on rainfall it is evident that the amount of precipitation between the periods of emergence and ripening has less influence upon the composition and yield of the crop than has either the amount of rainfall before the period of emergence or the total yearly rainfall.

The sugar beet during vegetation, E. Saillard (Monit. Sci., 5. ser., 6 (1916), I, No. 894, pp. 121-125).—This is a brief discussion of the effects of meteorological conditions on the sugar beet during the growing season. Averages are given for the 10-year period 1904 to 1913 for each week of August and September showing the rainfall, hours of sunshine, and mean temperature, and the yield of

beets per hectare, the weight of the entire plant, the weight of the roots, the yield of sucrose, the amount of sugar produced per week per hectare, and the amount of sugar produced per root per week. Some notes are also given on the reducing sugars present in sugar beets.

The present status of the sugar-beet seed industry in the United States, C. O. Townsend (U. S. Dept. Agr. Yearbook 1916, pp. 399-410, pls. 5).—The importance and possibilities of developing an American beet-seed industry capable of meeting the requirements of American sugar-beet growers are outlined and discussed, and cultural methods are described. The necessity for establishing uniform and fixed types is emphasized.

The present status of the sugar-beet seed industry in the United States, C. O. Townsend (Sugar [Chicago], 19 (1917), No. 5, pp. 176-180, figs. 6).—This is a reprint of the above.

[Experimental work with sugar cane], H. T. EASTERBY (Ann. Rpt. Bur. Sugar Expt. Stas. [Queensland], 16 (1916), pp. 34).—Work with sugar cane at numerous experimental centers in Queensland, in continuation of that previously noted (E. S. R., 35, p. 230) is reported.

Sweet clover: Growing the crop, H. S. Coe (U. S. Dept. Agr., Farmers' Bul. 797 (1917), pp. 34, figs. 11).—The field practices and cultural methods employed in the production of sweet clover are discussed in some detail.

Tests of 237 samples of hulled seed gave an average of 53.25 per cent germination, with 18.7 per cent of hard seed, as compared with an average of 11.8 per cent germination and 70.9 per cent hard seed for 45 unhulled samples. A further comparison of 22 samples each of southern and northern grown seed and of 28 samples of imported seed gave an average germination of 14, 37, and 56 per cent, respectively, with 60, 43, and 12 per cent of hard seed.

Means for the eradication of sweet clover are briefly outlined.

Timothy fertilization and culture, N. SCHMITZ (Maryland Sta. Bul. 202 (1917), pp. 159-178, figs. 3).—Fertilizing experiments with timothy begun in 1911, employing different commercial fertilizers as top-dressings, are reported and discussed, and field practices and cultural methods in timothy production deemed best for Maryland conditions outlined.

The fertilizer tests included a comparison of the effects of different fertilizers used alone and in various combinations; of different nitrogen carriers; of nitrate of soda, acid phosphate, and basic slag; of different rates and numbers of applications; and of spring versus fall applications.

The highest average yield of the 1912, 1913, and 1914 crops was secured from an application of 250 lbs. each of nitrate of soda and acid phosphate and 100 lbs. of muriate of potash, and amounted to 2.86 tons of hay per acre, an increase of 1.66 tons over the untreated checks. The lowest increases in yield, considered to be within the limits of experimental error, were secured from applications of basic slag and acid phosphate used alone.

An average yield of 2.34 tons was secured from a 300-lb. application of ammonium sulphate during 1913 and 1914 as compared with a yield of 1.49 tons from a similar application of dried blood. The gain over the untreated checks amounted to 0.98 and 0.13 ton, respectively. Nitrate of soda and nitrate of potash showed average yields of 2.21 tons each, a gain of 0.85 ton per acre. In a comparison of nitrate of soda, calcium cyanamid, and alpha tankage, the average yields for 1912 and 1913 were 2.71, 2.13, and 1.73 tons, respectively, which represented gains of 1.2, 0.62, and 0.22 tons per acre.

A summary of the data relative to the yields and net profits of nitrate of soda used alone, acid phosphate and nitrate of soda, and basic slag and nitrate of soda show that the average increase in yield amounted to 1.2, 1.35, and

1.08 tons per acre, respectively, with average net profits per acre of \$12.41, \$14.66, and \$9.57.

The average results of all applications of nitrate of soda used alone indicate that the 250-lb. rate gave the highest percentage increase, 61 per cent, while the 200-lb. rate gave the highest net profit, 152 per cent. The highest net profit from a single application of nitrate of soda, 359 per cent, was also obtained from a 200-lb. application.

The use of 150 lbs. of nitrate of soda and 250 lbs. of acid phosphate gave the highest single net profit, 341 per cent, of the different combinations tested, also giving the highest average net profit, 239 per cent. The average percentage of increase varied directly with the amounts of fertilizer applied, being highest, 69 per cent, with the heaviest application, 250 lbs. each of nitrate of soda and acid phosphate.

Applying half the fertilizer the first week in April and half the second week in May as compared with a single application of the whole amount the first week in April did not give as good results on the whole as the latter method. Any increase in yield secured from the two applications was deemed insufficient to pay for the extra labor involved.

The average net profit per acre of all fall applications of fertilizers was estimated to be \$5.88, while that of all spring applications was estimated at \$8.10.

Tobacco culture in North Carolina, E. H. Matthewson and E. G. Moss (North Carolina Sta. Bul. 237 (1917), pp. 40, figs. 13).—This is a detailed account of the production of flue-cured tobacco in North Carolina, including cultural and curing directions. A brief historical sketch of the introduction and development of the crop in the State and tabulated statistics on production by counties in 1909 and on sales in the old and new tobacco belts for 1910–11 and 1914–15 are also given.

Tobacco, J. F. BALDASSARRE (Bol. Min. Agr. [Argentina], 19 (1915), No. 16-12, pp. 752-826, pls. 2, figs. 32).—This is a detailed discussion of the economic and cultural conditions pertaining to tobacco in Argentina, including statistics on tobacco production in Argentina and other countries and importations and general notes on tobacco production in Cuba, Paraguay, and Brazil.

Notes on the composition of the ash in relation to the fertilizing of tobacco, S. Tijmstra (Meded. Deli-Proefstat. Medan, 10 (1916), No. 1, pp. 12-15).— This is a brief note on the effect of various fertilizer treatments on tobacco ash. The results agree with those obtained by Bylert and Hissink in similar experiments.

Agricultural seed inspected in 1915, C. P. SMITH (Maryland Sta. Bul. 203 (1917), pp. 179-230).—The results of purity and germination tests of about 1,200 official samples collected during 1915 are reported in tabular form and include red, mammoth, crimson, and alsike clovers, alfalfa, soy beans, cowpeas, timothy, orchard grass, millets, redtop, and Dwarf Express rape.

The "tolerance" table for purity tests previously noted (E. S. R., 36, p. 442) was applied to the above tests, and a similar table devised and illustrated to determine the tolerance for variations in germination tests.

The percentage of hard seeds in the samples of legume seeds tested is also reported.

Some information concerning the recognition of the Italian origin of red clover and alfalfa seed, G. Lakon (Landw. Jahrb., 49 (1916), No. 1, pp. 137-145, flgs. 2).—Numerous tests are noted for the determination of the origin of the red clover and alfalfa seed on the German market. It is demonstrated that with a knowledge of the weed flora of a region commercial seed from that region can be definitely identified.

Certain weed seeds have been designated as the "character" seeds in samples of red clover and alfalfa. Red clover samples from Italy were identified by the presence of Hedysarum coronarium and Phalaris paradoxa. Turkestan alfalfa was distinguished from alfalfa from other sources by the presence of Acroptilon picris. Out of 77 tests with alfalfa of supposedly Italian origin, 75 contained the following distinguishing weed seeds: Helminthia echioides, Trifolium supinum, Arthrolobium scorpioides, Hedysarum coronarium, Phalaris paradoxa, and Andropogon halepensis. The author states that while no one of these seeds can be regarded as characteristic as in the case of red clover, yet the weed flora as a whole is characteristic.

The origin of well-cleaned seed and mixed seed was obviously difficult to determine.

The disinfection of seeds with bromin, V. Artsikhovskii (Arcichovskij) and V. Stom (Zap. Sta. Isp. Sièm. Imp. Bot. Sad. (Ann. Inst. Essais Semences Jard. Imp. Bot. Pierre Grand), 3 (1915), No. 2, pp. 15, figs. 6).—The authors present data regarding the treatment of the seed of pumpkins, beans, peas, corn, flax, and wheat with 1 per cent bromin water for varying lengths of time. Their conclusion is that a 1 per cent bromin solution applied to the seed for half an hour will prove sufficient. See also a previous note (E. S. R., 35, p. 444).

Investigations in 1914 on the weeds occurring in the Government of Kherson, Russia, I. Pachoskii (Paczosky) (Trudy Būro Prikl. Bot. (Bul. Appl. Bot.), 8 (1915), No. 6, pp. 816-820; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, pp. 903, 904).—The object of these investigations was to devise a method for the study of field weeds and to study the root system of the weeds peculiar to the region.

The author holds that the only practical method for determining the degree to which a field is infested with weeds is to confine the observations to one or a few selected plats, after a careful examination of the actual field conditions.

The roots of Cirsium arvense were found to reach a depth of 20 ft.; those of Euphorbia virgata, 9.84 ft.; of E. glariosa, 8.53; of Centaurea scabiosa and Salvia nemorosa, 7.22 ft.; of Reseda lutea, 9.18 ft.; and of Melandrium album, 6.9 ft.

Crowfoot (Ranunculus arvensis), J. B. Martin (Compt. Rend. Acad. Agr. France, 2 (1916), No. 13, pp. 420-424).—A brief note on the occurrence and habit of growth of crowfoot. Suggestions are made for its control, and the value of copper sulphate, copper sulphate and sodium nitrate, and ferrous sulphate in combating the weed is discussed. Ferrous sulphate is reported as giving the best results.

The flea-seed, a new weed plant, T. G. B. Osborn (Jour. Dept. Agr. So. Aust., 20 (1916), No. 5, pp. 360-362, fig. 1).—This is a brief note on the appearance of flea-seed (Plantago psyllium) in South Australia.

[Notes on species of Xanthium and their destruction] (Instrucciones sobre el "Abrojo Grande" y su destrucción. Buenos Aires: Min. Agr., 1915, pp. 12, figs. 7).—Brief descriptive notes are given on a composite of X. macrocarpum, X. italicum, and X. strumarium, with suggestions for its eradication.

# HORTICULTURE.

The plant introduction gardens of the Department of Agriculture, P. H. Dorsett (U. S. Dept. Agr. Yearbook 1916, pp. 135-144, pls. 10).—A descriptive account of the plant introduction field stations or gardens situated at Miami and Brooksville, Fla., Chico, Cal., Yarrow, near Rockville, Md., and Bellingham, Wash., including information relative to methods of preventing the intro-

duction of injurious insects and diseases and recent introductions now being tested at the gardens.

Development and localization of truck crops in the United States, F. J. BLAIR (U. S. Dept. Agr. Yearbook 1916, pp. 435-466, figs. 13).—A statistical account of the development and localization of the truck crop industry in various parts of the United States.

Home vegetable gardening, C. E. Durst (Illinois Sta. Circ. 198 (1917), pp. 3-56, figs. 29).—A practical treatise on home vegetable gardening.

How to make the garden pay, E. Morrison and C. T. Brues (Boston: Houghton Mifflin Co., 1917, pp. VII+176).—A small popular manual for the intensive cultivation of home vegetable gardens.

Vegetable culture for all, Eva (London: Herbert Jenkins, Ltd., 1917, pp. XI+144, figs. 21).—A popular treatise with special reference to conditions in England.

The allotment book, W. Brett (London: C. Arthur Pearson, Ltd., 1917, pp. 92, figs. 27).—A popular treatise on amateur vegetable gardening, with special reference to conditions in England.

A book about potatoes and other vegetables, W. P. WRIGHT (London: Headley Bros., 1917, pp. 164, pls. 20, figs. 12).—A small practical treatise on vegetable gardening, in which special consideration is given to the petato.

Late cabbage, E. N. Reed (New York: John Wiley & Sons, Inc., 1917, pp. XIII+131, flgs. 38).—A practical treatise on cabbage culture based upon the author's experience and upon the results of investigations conducted by the experiment stations in the cabbage belt.

Adult characters in sunflower seedlings, T. D. A. COCKERELL (Jour. Heredity, 8 (1917), No. 8, pp. 361, 362, fig. 1).—In continuation of previous studies of the sunflower (E. S. R., 34, p. 237), the author calls attention to a number of variations in sunflower seedlings. These, it is concluded, are evidently inherited like other characters and may be obviously correlated with adult characters, whereas the manifestation of their effects may be limited to the seedling stage.

The effect of continued capillary watering, L. Daniel (Compt. Rend. Acad. Sci. [Paris], 163 (1916). No. 19, pp. 525-527; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 8 (1917), No. 1, pp. 84, 85).—Experiments conducted by the author with lettuce, chicory, cabbage, and radishes indicate that the continuous capillary watering of plants is much more beneficial than the usual intermittent watering employed in market gardening. Continued capillary watering gave seedling plants much in advance of those given the usual intermittent watering and also resulted in the development of more uniform and healthy subsequent growth.

Color as an indication of the picking maturity of fruits and vegetables, L. C. Corbett (U. S. Dept. Agr. Yearbook 1916, pp. 99-106, pls. 6).—The work of the Department has shown that immature apples when placed in storage develop various degrees of scald, depending upon the pigmentation or color development attained by the fruit up to the time of storage. As the apple matures and assumes its normal pigmentation, danger from scald becomes reduced. For best storage conditions, however, the normal pigmentation should not be too strongly developed, as overripe fruit suffers in storage as well as green fruit.

In the case of tomatoes, half-ripened red tomatoes will not produce a canned product or a catsup of bright red color, since the pigment in such fruits is not stable and fades slightly when the pulp is subjected to the temperatures required for sterilization or concentration. In fully ripe tomatoes the red pigment is fixed.

It is pointed out, in substance, that degree of color may be a measure of physiological activities in other fruits and vegetables as well as apples and tomatoes.

Arkansas Plant Act of 1917 and rules and regulations pursuant thereto (State Plant Bd. Ark. Circ. 1 (1917), pp. 16).—The law here presented is entitled "an act to prevent the introduction into and the dissemination within this State of insect pests and diseases injurious to plants and plant products of this State, to create a State plant board, and to prescribe its powers and duties."

Colorado's amended horticultural inspection law (Off. State Ent. Colo. Circ. 22 (1917), pp. 8).—This comprises the text of the law as amended in 1917.

Horticultural laws of Idaho (Jerome, Idaho: Lincoln County Times, 1917, pp. 16).—This pamphlet contains the text of the horticultural inspection, insecticide, and fungicide laws of Idaho.

Suggestions for the control of injurious insects and plant diseases. G. M. Bentley (*Tennessee Sta. Bul. 117* (1917), pp. 111-123, figs. 2).—A revised edition of Bulletin 106 (E. S. R., 31, p. 635).

Why, when, and how to spray, J. R. Cooper (Nebraska Sta. Bul. 158 (1917), pp. 3-20, figs. 13).—A brief review of Research Bulletin 10 (E. S. R., 87, p. 447).

The preparation and use of lime-sulphur in orchard spraying, W. J. Morse (Maine Sta. Doc. 523 (1916), pp. 11, figs. 2).—Directions are given for making home cooked lime-sulphur concentrate, together with dilution tables and brief suggestions on the use of lime-sulphur.

Practical guide to the culture of fruit trees in Chile, especially in the northern zone, A. Opazo G. (Cartilla Practica sobre Arboles Frutales que Debemos Propagar en Chile i Especialmente en la Zona Norte. Santiago de Chile: Serv. Agron. Rejion. i Enseñanza Agr. Ambulante, 1916, pp. 116, figs. 35).—Directions are given for the propagation, cultivation, care, and management of fruit trees adapted for culture in Chile, especially in northern Chile.

Rational fruit culture, H. C. DAVIDSON (London: Garden Life Press [1917], pp. [6]+127, figs. 48).—A practical treatise, with special reference to conditions in England.

The pear in Ontario, F. M. CLEMENT and O. J. ROBB (Ontario Dept. Agr. Bul. 249 (1917), pp. 28, figs. 24).—In this bulletin the authors give a summarized account of the pear industry in Ontario, together with suggestions relative to varieties, culture, harvesting, and marketing of pears.

Bush fruits, F. W. CARD (New York: The Macmillan Co., 1917, rev. ed., pp. XIII+409, pls. 16, figs. 58).—The present edition of this work (E. S. R., 10, p. 756) has been revised to include recent information on the subject.

Muscadine grape breeding, C. Deabing (Jour. Heredity, 8 (1917), No. 9, pp. 409-424, figs. 9).—A short general account of the work being conducted by the U. S. Department of Agriculture with muscadine grapes in the South, including a review of some of the results secured from intercrossing and hybridizing these grapes with other species.

Vinifera grapes in New York, R. D. Anthony (New York State Sta. Bul. 432 (1917), pp. 81-105, pls. 6).—This bulletin gives the results of experiments conducted at the station for several years in an attempt to cultivate the European grape (Vitis vinifera).

Since 1911 the station has had under trial more than 70 varieties of *V. vinifera* which were grafted on a miscellaneous collection of station seedlings ranging from 6 to 10 years old. Most of the plants fruited in 1913. By giving the vines winter protection and the usual grape sprays they have been kept in a healthy condition. Most of the Vinifera varieties have originated in regions with a longer season and a much warmer climate than that of New

York; hence, many of the kinds tested have been discarded. It is believed that the chief value of the Vinifera grape at present in the State is as a home-garden grape, for the commercial growers supplying local markets demanding high quality, and for the plant breeder. The varieties are discussed under the following general groups: (1) Desirable varieties for the grape regions of the State for the table and wine; (2) sorts worthy of testing in the more favorable parts of the State for table and wine; (3) kinds still on probation; and (4) varieties of little or no value in the State.

Relative to the culture of these grapes it is recommended that the eastern grower graft cuttings on phylloxera-resistant roots, such as V. riparia. The vines may be grown on the regular 2-wire trellis and protected through the winter by bending the trunk to the ground and covering with a few inches of earth. A replacing spur should be left at the base of the trunk to use in forming a new trunk when the old one becomes too stiff.

European grapes succeed in New York, F. H. HALL (New York State Sta. Bul. 432, popular ed. (1917), pp. 8-7).—A popular edition of the above.

Olive growing and production in Spain, J. M. PREGO (Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 12, pp. 1727-1733).—A general account of the olive industry in Spain, including information relative to the varieties grown, method of cultivation, development, and present condition of olive production.

Citrus stock experiments at Warm Baths, Transvaal, experimental orchard, C. A. Simmonds (Agr. Jour. So. Africa, 2 (1915), No. 11, pp. 196-205).—Brief notes are given on the condition and behavior of numerous citrus varieties, including oranges, tangerines, lemons, citrange, and grapefruit grafted on various stocks. The stocks used in the test, which has been carried on for a number of years, include rough lemon, Mazoe lemon, sweet orange, mandarin, sweet lime, Citrus trifoliata, shaddock, pomelo, Florida sour, and bitter Seville.

The origin and dispersal of Cocos nucifera, O. BECCARI (Philippine Jour. Sci., Sect. C, 12 (1917), No. 1, pp. 27-43).—In the present discussion the author reaches the conclusion that an Asiatic or Polynesian origin of the coconut palm is more probable than an American one, as suggested by Cook (E. S. R., 13, p. 714).

Note on the coffees and their culture at Lula, Mertens (Bul. Agr. Congo Belge, 7 (1916), No. 3-4, pp. 285-301, fig. 1).—Notes are given on the various coffees being tested at the Lula Agricultural Station, Stanleyville, Belgian Kongo, including observations on the diseases and other enemies of coffee at the station during the years 1914 and 1915.

The coffee industry of French Indo-China, L. P. Briggs (U. S. Dept. Com., Com. Rpts., No. 186 (1917), pp. 534-542).—In this account the author discusses the range of the coffee industry in French Indo-China, the climatic and soil conditions, varieties, plants resistant to insect attacks, cultural operations, harvesting and preparation for the market, enemies of the coffee tree, production and exportation, and the future of the coffee industry.

Filbert growing in the Puget Sound country, A. A. QUARNBERG (Seattle, Wash.: Puget Mill Co. [1917], pp. 36, figs. 19).—This booklet contains practical information on the culture of the European filbert (Corylus avellana) as at present practiced in the Pacific Northwest.

Further notes on the germination of belladonna seed, A. F. Sievers (Amer. Jour. Pharm., 89 (1917), No. 5, pp. 203-213, figs. 5).—The author briefly summarizes previous work along this line (E. S. R., 32, p. 626) and gives the results secured from three different methods of gathering belladonna seed with reference to their influence on germination. In the first method, the berries

were picked when ripe and succulent, the seed being at once removed from the pulp and dried. In the second, the berries were picked in a similar manner but allowed to dry spontaneously, which resulted in much molding and partial decomposition. In the third, the berries were allowed to remain on the plants until they were dry.

The first method produced the heaviest and the third method the lightest seed. The latter method is likely to result in the admixture of some immature seed. The first method produced seed of the best uniform color, while the second method resulted in seed of very poor color. The germination percentage was highest in the first and lowest in the third method. Seed from different individual plants was found to vary considerably in vitality.

Preliminary report on cooperative experiment [with Datura], C. M. Woodword and H. A. Langenhan (Bul. Univ. Wis., No. 829 (1916), pp. 51, 52).— A brief statement of progress made in breeding experiments with Datura species, with special reference to a determination of the inheritance of alkaloidal content. Analyses made in 1915 showed that the alkaloidal content of leaves varied much, both in the same plant and in different plants of the same species. The alkaloidal content of leaves in 1916 appeared to be more uniform.

Possibility of the commercial production of lemon-grass oil in the United States, S. C. Hood (Amer. Jour. Pharm., 89 (1917), No. 4, pp. 180-191).—This article is reprinted from the bulletin previously noted (E. S. R., 36, p. 538).

The sweet pea (Lathyrus odoratus) in the flower garden, A. C. Ghosh (Agr. Jour. Bihar and Orissa [India], 4 (1916), Double No., pp. 53-63, pls. 2).—In addition to cultural directions the varieties of sweet peas tested under the direction of the Botanic Garden at Sabour, India, are here described.

The culture and diseases of the sweet pea, J. J. TAUBENHAUS (New York: E. P. Dutton & Co., 1917, pp. XXIV+232, pls. 22, figs. 16).—A practical treatise on the subject, the successive chapters of which discuss the history, evolution, classification, and culture; culture of the sweet pea for seeds; culture of sweet peas under glass; diseases of greenhouse sweet peas; field diseases of sweet peas; diseases not yet known in America; insect pests; diseased seeds; physiological diseases; methods of control; and spraying.

The ornamental trees of Hawaii, J. F. Rock (Honolulu, Hawaii: Author, 1917, pp. V+210, pls. 2, figs. 79).—Descriptive accounts are given of the ornamental trees and shrubs of Hawaii, including references to fruit trees and ornamental vines. The plants treated or mentioned in the volume have been identified and are represented by specimens in the College of Hawaii herbarium. The author points out that it is possible that a few introduced and indigenous species as yet not identified or unheard of may not be included in the present work.

A bud variation of Pittosporum, A. D. SHAMEL (Jour. Heredity, 8 (1917), No. 8, pp. 357, 358, flg. 1).—The author illustrates and describes bud sports occurring in the ornamental hedge plant Pittosporum tobira variegatum for the purpose of calling attention to the possibility of studying and utilizing bud variations for the propagation of valuable commercial varieties of ornamental plants.

Hints on landscape gardening, Prince von Pückler-Muskau, trans. by B. Sicker, edited by S. Parsons (Boston: Houghton Mifflin Co., 1917, pp. XLV+196, pls. 38).—The present work comprises the second of a series of books (E. S. R., 19, p. 1042) undertaken at the suggestion of and with the cooperation of the American Society of Landscape Architects.

In part one of the present work the author presents hints on landscape gardening based upon the results secured in developing his private park at Muskau,

Silesia. Frequent reference is also given to observations made on various types of English landscape gardening. Consideration is given to the laying-out of a park; size and extent; inclosure; grouping in general, and buildings; parks and gardens; concerning the laying-out of the lawns of parks, meadows, and gardens; trees and shrubs and their grouping, and plantations in general; roads and paths; water; islands; rocks; earthworks and esplanades; and maintenance.

Part two contains a detailed description of the park in Muskau and its origin.

The natural style in landscape gardening, F. A. Waugh (Boston: Richard G. Badger, 1917, pp. 151, pls. 16, flg. 1).—A general work on landscape gardening, in which the author places special emphasis on the development of natural landscapes. As defined by the author the natural style of landscape gardening endeavors to present its pictures in forms typical of the natural landscape and made vital by the landscape spirit. The subject matter is presented under the general headings of what is meant, the native landscape, form and spirit, the landscape motive, principles of structural composition, the art of grouping, features and furnishings, and the open field.

# FORESTRY.

Forest laws (N. H. Forestry Com. Circ. 7, rev. (1917), pp. 44).—This pamphlet gives the State laws relating to forestry in general and particularly to the protection of forests from fire, the control of the white pine blister rust, the purchase and development of State forests, and the possibilities for woodlot owners to secure help in reforesting waste lands and improving woodlots.

Annual report for the year ended October 31, 1316, Department of Conservation and Development (*Rpts. Dept. Conserv. and Develop., N. J., 1916, pp. 84, pls. 18, figs. 2*).—In addition to the report of the department as a whole, the reports of the State geologist, State forester, and State firewarden are given.

Opening up the National Forests by road building, O. C. MERRILL (U. S. Dept. Agr. Yearbook 1916, pp. 521-529, pls. 3).—A review of legislation dealing with road building in the National Forests, including an account of the work accomplished along this line.

The work of the forest department in India, edited by R. S. Troup (Calcutta: Govt., 1917, pp. [6]+65, pls. 13).—This publication presents the main facts connected with the work of the forest department in India and sketches the outlook for future expansion. The subject matter is presented under the general headings of history of the forest department; area, classes, and types of forests; forest policy and legal control; administration and staff; research; forest organization and exploitation; forest products; forest industries; financial results; and future prospects and requirements.

Silviculture, E. MARSDEN (Ann. Rpt. Bd. Sci. Advice India, 1915-16, pp. 123-129).—A brief review of silvicultural operations conducted by the forest service of India, including a list of publications for the year 1915-16.

The relation of the storage of the seeds of some of the oaks and hickories to their germination, C. C. Delavan (Rpt. Mich. Acad. Sci., 17 (1915), pp. 161-163).—Different methods of storing oak and hickory seeds were compared at the University of Michigan to determine the influence of storage on the germination of the seeds. Three species of hickory, three species of the white-oak group, and two species of the black-oak group were included in the test.

The work showed in brief that a cold, even temperature, even if the atmosphere is very moist, is better than a warm, drier condition of storage. The

best results from the standpoint of germination were secured by storing the seeds in closed but unsealed fruit jars placed in an ice box.

Evergreen trees for Iowa, G. B. MacDonald (Iowa Sta. Bul. 170 (1917), pp. 31-59, figs. 31; abridged ed., pp. 16, figs. 7).—This bulletin lists the most desirable evergreens to be used in Iowa for shelter belts, windbreaks, and ornamental planting, and gives brief descriptions of their characteristics and value for various purposes, as well as methods of planting and growing.

The structure and identification of Queensland woods, N. W. Jolly (Dept. Pub. Lands, Queensland, Forestry Bul. 1 (1917), pp. 14, pls. 5).—A descriptive account of the wood structure, with illustrations, of some 45 species of the more common trees of Queensland.

Utilization of ash, W. D. STERRETT (U. S. Dept. Agr. Bul. 523 (1917), pp. 52, pls. 10, figs. 3).—This bulletin discusses the value of ash for different uses, gives the amount of the different species of ash used in various industries, and indicates methods by which owners may utilize their ash timber profitably. An account is also given of the properties of ash wood, including results of tests conducted by J. A. Newlin with different species.

Grass trees: An investigation of their economic products, J. C. EARL (SQ Aust. Dept. Chem. Bul. 6 (1917), pp. 19, pls. 5).—A study of the grass trees, blackboys, or yackas (Xanthorrhæa spp.) of South Australia, with special reference to their botany, distribution, and exploitation for resin. A short chemical study of the resin extracted is included.

Note on Indian sumac (Rhus cotinus), PURAN SINGH ([Indian] Forest Bul. 31 (1916), pp. 12).—The author calls attention to the possibility of using the Indian sumac (R. cotinus) as a source of tannin, and gives an account of the cultivation, preparation, and quality of European sumacs (Rhus spp.) for this purpose.

Notes on Funtumia elastica and Funtumia hybrids, MINY (Bul. Agr. Congo Belge, 7 (1916), No. 3-4, pp. 246-267, figs. 14).—This comprises notes and observations on the growth and rubber-yielding value of F. elastica and other Funtumia hybrids as observed in plantations in the oriental Province of Belgian Kongo.

Investigations on the mechanism of the cicatrization of tapping wounds among rubber-yielding plants, F. Heim (Bul. Off. Colon. [France], 10 (1917), No. 110-111, pp. 95-102, pl. 1).—The author here summarizes the results of studies conducted by J. Maheu relative to the healing of wounds and development of new latex-yielding ducts among African rubber plants. The text is accompanied by a number of figures showing the process of cicatrization. The results show, in brief, that the tapping operation should consist in making numerous small wounds rather than large wide wounds inasmuch as abnormal growths are apt to occur on the latter wounds, thereby interfering with the reestablishment of the latex ducts.

Economic forest products, R. S. Pearson (Ann. Rpt. Bd. Sci. Advice India, 1915-16, pp. 130-137).—A report of investigations conducted by the forest service of India with economic forest products, including a list of publications relating thereto published during 1915-16.

Marketing woodlot products in Tennessee, W. D. Sterrett (Resources Tenn., 7 (1917), No. 3, pp. 111-195, figs. 19).—Information is given relative to the woodlot regions of the State; native tree species and their uses; available markets, classed both by products and by species; lumber and log values; best methods of estimating and marketing various woodlot products; and the care of cut woodlot products. A directory of wood-using firms is included.

#### DISEASES OF PLANTS.

A method for studying the humidity relations of fungi in culture, N. E. Stevens (*Phytopathology*, 6 (1916), No. 6, pp. 428-432).—A description is given of a method used by the author in maintaining known humidities in small chambers which is applicable to the study of fungi in culture or growing on small fruits. It consists in keeping the cultures of fungi or the affected fruits in an atmosphere which is maintained at a constant humidity by exposure to an aqueous solution of sulphuric acid of known specific gravity.

Celluloid cylinders for inoculation chambers, E. E. Hubert (*Phytopathology*, 6 (1916), No. 6, pp. 447-450, fig. 1).—The author describes a cylinder made of sheet celluloid which has proved adapted to use in inoculation experiments on tree seedlings and similar hosts.

Nematode technique, T. B. MAGATH (*Trans. Amer. Micros. Soc.*, 35 (1916), No. 4, pp. 245-256, figs. 6).—The methods here presented are intended to serve as a guide for future work. While applicable for free-living nematodes, the methods have been worked out particularly for the parasitic forms.

Presence of nitrites and ammonia in diseased plants. Its significance with regard to crop rotation and soil depletion, P. A. Boncquet (Jour. Amer. Chem. Soc., 38 (1916), No. 11, pp. 2572-2576).—The author, having continued some phases of the work previously participated in by him (E. S. R., 34, p. 645), states that in beets Bacillus morulans is able to reduce nitrates not only to nitrites but also partly or wholly to ammonia, these substances never being found in these tests apart from pathological indications.

Mosaic disease of tobacco was associated with a filterable organism which showed considerable reducing power and which was absent from normal leaves. An organism provisionally named *Streptococcus solani* n. sp. was present uniformly in certain potato vines and leaves. This proved to be an active nitrate reducer. Traces of ammonia were also detected. This organism may prove to be connected with brown streak and blossom abortion of potato. Some other plants which looked sickly gave a decided nitrite reaction, the intensity thereof corresponding to the severity of the sickly appearance shown by the plants.

Nitrites have not been detected in any plant tissue which can, in strictness, be called normal. The disturbance is ascribed to a partial and local nitrogen starvation of the tissues, as well as to mechanical laceration due to ulcer formation by the bacteria.

It is thought that soil depletion has a fundamental relation to nitrate reduction, a lack of rotation favoring the accumulation of nitrate-reducing organisms.

The influence of Æcidium clematidis on the leaves of its host, L. Montematini (Riv. Patol. Veg., 8 (1916), No. 8-9, pp. 165-176).—Having shown previously (E. S. R., 17, p. 981) that vegetable parasites produce in their hosts at first a stimulating, but later a depressing effect, the author has made a study of leaves of Clematis vitalba attacked by Æ. clematidis, from which it is concluded that the acceleration observed is a consequence of the increase of chlorophyll in the infested leaves. While the ash weight per unit of area was increased by the fungus attack, the ash weight per unit of dry matter was lessened thereby. Assimilation and transpiration appeared to be more energetic in diseased leaves than in sound ones, as shown by the total ash content. The calcium, however, was somewhat less in case of the diseased leaves, which showed a considerable increase in silica. These findings are compared with some reported by Pavarino (E. S. R., 18, p. 347).

Work connected with insect and fungus pests and their control (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Montserrat, 1915-16, pp. 23-26).—Besides notes on cotton stainers, an account is given of attempts to control peanut leaf rust (Uredo sp.), which was accomplished with Bordeaux mixture; of a serious and spreading wilt of pineapple, involving root decay; and of two diseases of papaya, one of which appeared on the leaves in association with Asperisporium caricæ in an unsuitable situation, the other and more important one attacking stems and fruit and resembling considerably a disease reported from Barbados as produced on stems, leaves, leaf stalks, and fruits by a species of Colletotrichum.

Reports of the botanical laboratory and laboratory for plant diseases, L LINSBAUER, F. ZWEIGELT, and H. ZUDERELL (Programm u. Jahresber, K. K. Höh. Lehranst. Wein u. Obstbau Klosterneuburg, 1914-15, pp. 91-101; 1915-16, pp. 117-130).—Continuing previous work (E. S. R., 33, p. 444), the first of these two reports, along with insect enemies and other matters, deals with Fusicladium, Penicillium, Gymnosporangium sabinæ, Mycosphærella scutina, Puccinia pruni-spinosæ, and leaf curl as related to orchard plants; Sphærotheca mors-uvæ on gooseberry; Plasmopara vitiæola on grape; Plasmodiophora brassicæ, Sclerotinia libertiana, Colletotrichum lindemuthianum, Bremia lactucæ, and Peronospora effusa on vegetables; Asteroma rosæ and Oidium cuonymi japonici on ornamental plants; Erysiphe tortilis, Cæoma cuonymi, Lophodermium macrosporum, L. pinastri, P. effusa, Ustilago tragopogonis, and Ramularia violæ on wild-growing plants.

The second report also gives data regarding Septoria piricola, Cephalothecium roseum, Phytophthora cactorum, Exoascus bullatus, and E. deformans on fruit trees; Boytrytis and Oldium on grape; Pseudomonas phaseoli, P. campestris, Puccinia chondrilla, and P. glumarum on field or garden plants; Gymnosporangium clavariaforme, Glaosporium tilia, G. nervisequum, and Phragmidium subcorticium on various ornamentals.

Some new or rare plant diseases, L. Montemarini (Riv. Patol. Veg., 7 (1915), No. 8-9, pp. 225-237; 8 (1916), No. 8-9, pp. 177-185).—In the first of these reports, continuing previous work (E. S. R., 30, p. 349), the author notes a leaf scorch of Syringa vulgaris associated with Cladosporium syringa n. sp.; one of Anthurium with Chatodiplodia anthurii n. sp., Glomerella anthurii n. sp., and Colletotrichum anthurii; a leaf spot of Corylus avellana with Cercospora coryli n. sp.; of Quercus sessiliflora with Septoria sp. and Phyllosticta italica n. sp.; of Camellia japonica with Alternaria camellia; of Cratægus with Hadrotrichum populi; a leaf dieback of yucca with Cylindrosporium yucca n. sp.; a leaf perforation of peony with Coniothyrium paonia n. sp.; and a Cicinnobolus, very similar to C. cesatii evonymi noted in France by Vuillemin (E. S. R., 24, p. 352), attacking Oidium on oaks.

In the second report, the author notes a bacteriosis of chestnut leaves; a leaf spot of Tilia ascribed to a fungus which is considered a new variety, Phyllosticta bacteroides minima; a fruit disease of pomegranate due to Ceuthospora punicæ; a leaf shot-hole and laceration of Acanthus connected with a fungus described as a new variety, Septoria acanthi romana; a leaf curl of cherry associated with Exoascus cerasi; a leaf spot of Cratægus oxyacantha associated with P. bacillaris n. sp., supposedly the pycnidial stage of Venturia cratægi; and a cucurbit leaf spot associated with several fungi named as probably saprophytic, with Cercospora cucurbitæ, P. cucurbitacearum, Ascochyta sp., and the new species S. cucurbitæ and Leptosphæria cucurbitæ, also supposed to be parasitic.

Phytopathology, F. A. STOCKDALE (Ann. Rpt. Dept. Agr. Mauritius, 1915, pp. 14-16).—The general conditions throughout 1915 are said to have been

somewhat unfavorable to the spread of fungus diseases in this region. The extreme dryness favored the spread of a root disease of sugar cane due to a weakly parasitic Marasmius. Pithy deterioration of White Tanna cane, apparently due to a bacterium, was prevalent in certain districts, and some other varieties were affected. The gumming disease of sugar cane noted during the early part of the year (E. S. R., 34, p. 843) did not spread after May. Red rot (Colletotrichum falcatum) occurred in September and October on one estate, following an attack by borers (Diatræa striatalis). Smut (Ustilago sacchari) came under observation here this year for the first time.

The leaf disease of Arabian coffee due to *Hemileia vastatrix* was less common this year than usual. It was controlled by Bordeaux mixture in one instance.

The manioc leaf and stem disease ( $Glamosporium\ manihotis$ ) was again common in some localities, causing defoliation in September. Some recently introduced varieties appear to be somewhat resistant to this disease.

A leaf spot of pistachio, due to *Uredo arachidis*, was again observed. The most serious leaf spotting of pistachio was due to *Cercospora personata*, which caused much damage to introduced varieties.

Leaf disease (*Phytophthora infestans*) of potato was common during July to September, inclusive. Cooperative spraying gave encouraging results. Spraying should begin early, and should continue at intervals of 8 to 10 days, owing to heavy dews in July and August.

Tomatoes raised from imported seeds suffer with leaf disease, but the local pomme d'amour is measurably resistant. Sleeping disease (Fusarium lycopersici) and a collar rot are common and injurious. Egg fruits (Solanum melongena) were badly affected with stem blight during March and April. A root disease of she oak (Casuarina equisetifolia) is under investigation. Turkish tobacco at Pamplemousses failed on account of attacks by an Erysiphe.

Lists are given of garden plants examined during the year, diseases noted, and causative organisms.

Report of the microbiologist, H. M. NICHOLLS (Tasmania Agr. and Stock Dept. Rpt. 1913-14, pp. 28, 29).—In a brief report which also deals with insect pests, the author notes the first appearance in Tasmania of cruciferous clubroot (Plasmodiophora brassica) and of cabbage leaf spot (Glasporium concentricum). Considerable injury is done by a rust causing dieback in orchards.

The principal potato diseases noted were dry rot (Fusarium solani) and scab (Oospora scabies). The dry rot due to Spondylocladium atrovirens was noted here for the first time.

Notes relating to the Gymnosporangia on Myrica and Comptonia, B. O. Dodge and J. F. Adams (Mycologia, 9 (1917), No. 1, pp. 23-29, pls. 2, fig. 1).— A study has been made, with inconclusive results, regarding the relationships of a fungus found in 1916 to cause certain changes, which are described, in Comptonia. It is thought that the fungus may prove to be a relative or member of the genus Gymnosporangium, possibly identical with G. myricatum or Ecidium myricatum on Myrica.

Studies in the life histories of some species of Septoria occurring on Ribes, R. E. Stone (Phytopathology, 6 (1916), No. 6, pp. 419-427, figs. 2).—Additional investigations have confirmed the conclusion of the author that S. ribis has for its perfect stage Mycosphærella grossulariæ (E. S. R., 36, p. 246). The perfect stage has been reported on R. grossularia and R. nigrum in Europe and possibly on R. rubrum, but in North America it has been collected only on R. nigrum. M. aurea n. sp. is described as the perfect stage of S. aurea. This fungus is said to be more limited in its range, being known only in North America on R. aureum.

The Uredinales found upon the Onagraceæ, G. R. BISBY (Amer. Jour. Bot., 3 (1916), No. 10, pp. 527-561).—This is a study of the characters and correlations of Uredinales on Onagraceæ.

It is conceded that a perfectly consistent treatment of all the evening primrose rusts is impossible at this time, this study attempting rather to draw attention to some of the more insistent questions which arise. These rusts appear to fall into three somewhat definite groups, those with teliospores adherent in layers, those with teliospores free and short-ellipsoid, and those with teliospores free and long-ellipsoid, with a fourth group, the members of which may really belong to the second and third.

The main points brought out are the grouping of the long-cycled, autœcious forms of Puccinia upon the Onagraceæ into one species and the considerations involved; some notes upon heteræcious forms, which include the Onagraceæ in their life cycle; some correlations between species and races; and keys based respectively upon the life history, upon the spore forms independently, and upon the host (indicating also the geographic distribution). The hosts and rusts, an index to which is also given, present many parallelisms in their evolution.

Endophyllum-like rusts of Porto Rico, E. W. OLIVE and H. H. WHETZEL (Amer. Jour. Bot., 4 (1917), No. 1, pp. 44-52, pls. 3).—A list given by the authors, with discussion of some rusts collected in Porto Rico early in 1916, includes, as new genera, Botryorhiza, represented by B. hippocratex, and Endophylloides, represented by E. portoricensis; also as new combinations, Endophyllum circumscriptum, E. wedelix, E. decoloratum, and E. stachytarphetx.

The barberry bush and black stem rust of small grains, I. E. MELHUS and L. W. Durrell (Iowa Sta. Circ. 35 (1917), pp. 4, figs. 6).—Attention is called to the relation of the common European barberry (Berberis vulgaris) to the black stem rust of cereals, for which this barberry acts as alternate host. The author recommends the eradication of all of the common European barberries. If such plants are desired, the Japanese species (B. thunbergii) may be substituted, as this is considered immune to rust attack.

Sclerotinia libertiana on snap beans, J. A. McClintock (*Phytopathology*, 6 (1916), No. 6, pp. 436-441, figs. 2).—A detailed account is given of a serious disease of a fall crop of snap beans which was investigated at the Virginia Truck Experiment Station, a popular account of the disease having already been noted (E. S. R., 36, p. 647).

The investigations have shown that the trouble is due to S. libertiana, and some evidence is said to have been obtained indicating varietal resistance toward the organism. In culture the fungus isolated from beans produced sclerotia, which differed in size and shape from those produced by the lettuce drop organism, thus suggesting that the former organism is a special strain of S. libertiana.

The Peronospora disease of maize, A. A. L. RUTGES (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 22 (1916), pp. 50, pls. 7).—This is a study of the lijer disease, said to be the most serious affecting Indian corn in Java, where it has been present for at least 25 years, occurring all over that island and Madura, and also in Achin, but never at an altitude of more than 4,000 feet.

The symptoms are described as differing according to the age of the plant. The disease is caused by  $P.\ maydis$ , which is provided with conidia, chlamy-dospores, and oospores, both the latter being found in decaying portions of young plants, especially in the leaf sheaths. Young plants are known to be susceptible to infection by conidia, but this is not known to occur normally in

the field. Infected soil gave negative results. Seed which had been placed in water at 60° C. showed twice as high a degree of infection as did the control seed, owing supposedly to the weakening effect of the hot water upon the seed.

Flower-bud and boll shedding of cotton in the Horin Province, Nigeria, T. Thornton (Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 379-384).— In this account, previously noted from another source (E. S. R., 34, p. 844), it is stated that native and imported cottons behaved alike as regards shedding. The nature of the influence of sunshine and humidity was not determined. Seed were preserved from a plant which retained all its blooms and ripened all its bolls, with a view to breeding a variety resistant to the extreme conditions and quick changes prevalent in this region.

Onion mildew, H. BLIN (Rev. Hort. [Parts], 88 (1916), No. 9, pp. 141, 142).—A mildew disease of onions, studied since 1913, is said to have been due to Peronospora schleideni, though Macrosporium parasiticum sarcinula was often present, and apparently took a certain part in the alteration observed. For the protection of plants from attack, the author suggests the use of Bordeaux mixture made up of 3 per cent copper sulphate and 2 per cent lime.

Some potato problems, P. R. Cowan (Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 8 (1915–16), pp. 59-63).—Noting the growing importance of disease as affecting returns from potato culture in Canada, the author discusses varietal susceptibility and the symptoms of the various potato diseases. The several means of control considered effective are outlined.

Cryptogamic diseases of sugar cane, R. Averna Saccá (Bol. Agr. [Sao Paulo], 17. ser., No. 8 (1916), pp. 610-641, figs. 27).—This is a condensed account of information collected during several years regarding sugar cane diseases as related to Schizophyllum commune (S. alneum), Valsaria subtropica, Linospora sacchari, Leptosphæria sacchari, Euryachora sacchari, Cytospora sacchari, Nectria sp., Otthia sp., Fusarium sp., Vermicularia sacchari, Colletotrichum falcatum, Lasiodiplodia theobromæ, Coniothyrium sacchari, Phyllosticta sp., Dendrophoma saccharicola, Sphæropsis pseudodiplodia, and Cladosporium graminum.

Pathology and physiology of tobacco in the Crown lands, H. Jensen et al. (Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 5 (1913), pp. 7-78, 122-130, 137, 197, 198, pls. 8).—These selections include the botanical and phytopathological portions of a somewhat extended report embodying materials taken by the author from his own work and from that of M. Raciborski, O. de Vries, and M. Treub.

Tobacco diseases, or causes thereof as dealt with, include *Phytophthora nicotianæ* (here considered as possibly identical with *P. infestans*), gummosis (bacterial), leaf mosaic, tjakar, various fungl, nematodes and other animals, and diseases of undetermined causation. The abnormality of the flowers, characterized by their turning or remaining green, mutants with double blooms, three-parted seedlings, the influence of light on germination, and the influence of colored light on desiccation are also discussed.

Lanas disease of tobacco in the Crown lands, H. Jensen (Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 1 (1913), pp. 35, pls. 5).—Having made a study of a disease supposedly identical with that reported by J. Van Breda de Haan (E. S. R., 8, p. 237) as due to a fungus which that author described as a new species under the name Phytophthora nicotianæ, the present author distinguishes between this disease and one characterized by a gummosis (but showing a somewhat similar leaf wilt) by employing rather arbitrarily for these two diseases the Javanese terms lanas and lier, respectively.

Lanas may attack in any one of four forms, namely, entire young plantlets on the seed bed, the crown at any age, the upper part of the stalk of grown plants, or the leaves thereof. Comparisons are made with tobacco diseases elsewhere.

Spraying affected plants and soil with fungicides and removal of affected plants are recommended.

Gummosis in tobacco, H. Jensen (Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 6 (1914), pp. 3-10, fig. 1).—The author gives the results of studies on the relation between lanas in the Crown lands and gummosis at the Deli station. These diseases may prove to differ but little, except in the greater severity noted in the former case.

Experiments carried on simultaneously by the author in the Crown lands and by J. A. Honing at Deli seemed to indicate that a strain of Kanari tobacco is somewhat resistant to diseases of this type, attaining more vigorous growth than either of the other two strains tested.

Leaf roll in tomatoes, H. T. Güssow (*Phytopathology*, 6 (1916), No. 6, p. 447).—The author reports a disease of tomatoes at Lethbridge, Alberta, which shows phenomena closely resembling the leaf roll in potatoes, and he suggests that the disease is similar to one previously described from Austria by G. Köck, in which no parasitic organism was found. The Canadian specimens are said to have appeared sound with the exception of the rolling of the leaves.

Watermelon diseases, W. A. Orton (U. S. Dept. Agr., Farmers' Bul. 821 (1917), pp. 18, flgs. 11).—Popular descriptions are given of a number of diseases to which the watermelon is subject, together with suggestions for their control. Among the more common and destructive diseases are watermelon wilt, root knot, anthracnose, and stem-end rot. Descriptions are also given of several minor diseases.

The varietal relations of crown gall, J. K. Shaw (Science, n. ser., 45 (1917), No. 1167, pp. 461, 462).—Attention is called to the various forms of crown gall occurring on apple trees, and the author raises the question as to whether the different forms may not be due to varietal differences in the host plants. During the past few years several thousand apple trees of many varieties have been propagated on their own roots by means of the common whip graft, the seedling nurse root being cut off at the end of about two seasons' growth, thus leaving the scion growing on its own roots. It has been observed that where crown gall is present on such trees there is a tendency for a given variety to have only a single form of the disease. The Jewett shows usually the hard form of the gall, the Red Astrachan the simple form of the hairy root, and the Oldenburg the woolly knot form with many soft fleshy root growths. Some varieties on their own roots seem to be largely if not entirely immune to this disease, and it is suggested that this fact may offer a solution of the problem of the prevention of crown gall.

Fire blight, F. Létourneau (Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 8 (1915-16), pp. 42-45).—Fire blight is said to be the worst disease of fruit trees in the Province of Ontario, attacking chiefly pear, but also apple, quince, and even plum, hawthorn, and mountain ash. The disease is said to be peculiar to North America, occurring all over the United States and in Ontario, Quebec, and British Columbia. The various forms and effects of attack are discussed, as are also the life cycle and means of control.

Dieback of apple trees, caused by Cytospora leucostoma, P. A. VAN DER BIJL (BYL) (So. African Jour. Sci., 12 (1916), No. 12. pp. 545-557, pls. 6, flgs. 4).—
The author describes a serious dieback of apple attributed to C. leucostoma, which is said to appear also in the same, or a closely related form, on peach, plum, and apricot trees. The fungus grows well in the laboratory on a number

of media, developing pycnidia. The ascus stage has not been observed. The fungus appears to flourish through a rather wide range of temperature, growth being vigorous between 25 and 30° C. (77 and 86° F.). The mycelium is septate and branched.

Control measures suggested include destruction of diseased parts and cleansing sprays in winter.

New facts regarding the period of ascospore discharge of the apple-scab fungus, L. Childs (Oregon Sta. Bul. 143 (1917), pp. 3-11, figs. 2).—A report is given of a study of the activity of the apple-scab fungus made in Oregon during 1916 in order to determine the time at which primary infection could be expected and the bearing that it would have on the first application of a fungicide. The investigation has shown that there is a correlation between spore ejection and the prevailing weather conditions, the number of periods of ascospore discharge, and the length of ascospore activity during the season.

Mature ascospores were first ejected at Hood River on March 20, 1916, and the last ejection observed was on June 27. At Corvallis this activity was first noted on February 25, and the discharge was abundant as late as May 20, after which no observations were made. It was observed that, as a rule, the heaviest spore ejection occurred during the first two or three days of a rainy period, gradually becoming less toward the end of the wet weather.

This study is considered to have demonstrated that the delayed dormant application of fungicides given while the leaves are small and undeveloped can not be safely dispensed with in the Hood River and Willamette Valleys, as the ejection of ascospores begins before the foliage is even started. Owing to the great length of ascospore activity, it is stated that orchardists are not safe in omitting any of the later spring sprayings, even though conidial infections are not present.

The black knot of plum and cherry, C. B. Hutchings (Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 8 (1915-16), pp. 85-88, fig. 1).—Black knot, prevalent in Great Britain, the United States, and Canada wherever wild or cultivated plums and cherries grow, is said to be particularly severe in the Maritime Provinces, Quebec, parts of Ontario, and New York State. Notable exceptions occur in case of the plum and cherry orchards of the Niagara peninsula, owing to the thoroughness of the control measures there employed. Early removal and complete destruction of all knots before maturing is considered to be the simplest and most effective of all treatments for black knot.

Rougeot of grapevines, H. Faes (*Prog. Agr. et Vit.* (*Ed. VEst-Centre*), 37 (1916), No. 45, pp. 444-448, fig. 1).—This is chiefly a discussion of the views of several investigators on the grapevine disease known for some years in Switzerland and elsewhere in Europe and designated by such descriptive names as rougeot, red scald, etc. The evidence is considered to favor the view of Müller-Thurgau (E. S. R., 30, p. 452) that the disease is associated with the blocking of the vessels by *Pseudopeziza tracheiphila*.

A Pythiacystis on avocado trees, H. S. FAWCETT (Phytopathology, 6 (1916), No. 6, pp. 433-435; Rpt. Cal. Avocado Assoc., 1916, pp. 152-154).—The author reports a disease of avocado trees in California in which the bark is killed and slightly sunken areas produced. It is accompanied by the exudation of gum. The disease is said to occur most frequently on trunks not far from the surface of the soil, and it is found not only on the trunks of larger trees but on small seedlings, especially if the latter have been overwatered.

Studies of the disease showed the presence of a Pythiacystis similar to *P. citrophthora*, and it is thought that under certain conditions this fungus may become at least a wound parasite of avocado trees. The fungus was isolated from

two different specimens of avocado trees, was introduced into trunks of avocado trees in two different seasons, and produced effects similar to those on the trees from which it was isolated.

Banana disease on the Salayer Islands, A. B. Rijks (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 21 (1916), pp. 16, pls. 4).—Observations made since November, 1915, are reported on the disease which is the cause of increasing loss to banana culture in several islands of the Salayer group. The author gives an account of some conditions apparently related to the prevalence of the disease, such as location, climate, soil, culture, light intensity, and varieties differing in resistance to the disease. The trouble appears in the young roots, later attacking the older ones and almost completely suppressing the root system of the plant.

Characteristics of citrus canker and of the causal organism, R. A. Jehle (Quart. Bul. Plant Bd. Fla., 1 (1917), No. 2, pp. 24-47, figs. 20).—This paper aims to give such information, additional to that previously noted (E. S. R., 36, p. 352), as may enable citrus growers to obtain an adequate knowledge of citrus canker.

Apparently the disease is distributed by such mechanical carriers as rain, dew, insects, and in particular, men and domestic animals. Experiments on young plants kept in screened cages, which are described, indicated the causal agency of *Bacterium* (*Pseudomonas*) citri. Probably ripe fruits are not attacked, but they may serve as mechanical carriers.

The symptoms are described as being very similar on all the parts attacked. On twigs the cankers do not penetrate the wood. The period within which infection becomes obvious, after inoculation, may vary greatly, being influenced by weather or seasonal conditions and the vigor of the host, as are also the prevalence and severity of the canker.

Cooperative work for eradicating citrus canker, K. F. Kellerman (U. S. Dept. Agr. Yearbook 1916, pp. 267-272, pls. 4).—A popular description is given of the citrus canker due to Pseudomonas citri, together with an account of the cooperative work for the eradication of this disease carried on by the Department of Agriculture and various Gulf States as outlined.

Department of citrus canker eradication, F. STIRLING (Quart. Bul. Plant Bd. Fla., 1 (1917), No. 2, pp. 50, 51).—Giving data for 1914 to 1916 which he has compiled on the canker eradication work conducted in cooperation with the U. S. Department of Agriculture, the author states that citrus canker has been found on 441 properties in 22 Florida counties, there were still being classed as infected in 1916, 150 properties, 12 properties in 3 counties showing active infection at that time, of which 4 cases were regarded as new. The number of infected trees showed high maxima in August, of 1914, May and August, of 1915, and a much lower maximum in June, 1916, the range during that year being much lower than that for the other two years.

Citrus scab, H. S. Fawcett (Phytopathology, 6 (1916), No. 6, pp. 442-445).—
The author reviews and criticizes the conclusions of Grossenbacher regarding the cause of citrus scab (E. S. R., 36, p. 352). He also reviews some of his own investigations carried on at the Florida Experiment Station (E. S. R., 27, p. 653), which are considered to indicate definitely that Cladosporium citri is the cause of citrus scab.

Report of the mycologist, W. Nowell (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Montserrat, 1915-16, pp. 9-12).—Limes in the district near Plymouth exhibited a progressive dieback of the branches, and another, supposedly distinct therefrom, of the roots. The symptoms, which are discussed for each case, suggest that both troubles result from conditions unfavorable to vigorous growth in this locality. The conditions considered as significant are the

amount of available water, degree of exposure to wind, and possibly some factor affecting nutrition.

On the dieback disease of Paulownia tomentosa caused by a new species of Valsa, T. Hemmi (Bot. Mag. [Tokyo], 30 (1916), No. 357, pp. 304-315, figs. 4; abs. in Mycologia, 9 (1917), No. 1, p. 40).—Since 1914 the author has studied a dieback of P. tomentosa, due to a fungus described as a new species, V. raulownia, and said to be an almost omnivorous saprophyte. It attacks all parts of these trees of any age, but only at points where they have been injured, producing a layer of dead cells. Winter injury constitutes an important contributing factor in the vicinity of Sapporo, Japan.

Diseases of woody plants in North Africa, R. MAIRE (Bul. Sta. Forest. Nord Afrique, 1 (1916), No. 4, pp. 121-130, pl. 1, figs. 4).—Arbutus unedo in Algerian forests is subject to a disease producing a crowding together of the leaves, which persist after they become dead and dry, giving the appearance of a small witches' broom. The trouble is said to be due to a fungus described as Exobasidium unedonis n. sp., which is further discussed. The same branches as bear the above fungus show another fungus described as Glæosporium conviva n. sp., and a third designated as Phoma arbuti n. sp. Rosa sempervirens near Algiers is frequently attacked by a fungus thought to be new, and described as Phragmidium rosæ-sempervirentis.

The influence of certain climatic factors on the development of Endothia parasitica, N. E. Stevens (Amer. Jour. Bot., 4 (1917), No. 1, pp. 1-32, figs. 3).—The author made a study during 1914 and 1915 of the behavior of chestnut blight on trees inoculated with E. parasitica. The experimental tracts ranged from Concord, N. H., to Charlottesville, Va., this stretch of country including a transition region for several important plant diseases which are named.

The average annual growth laterally of the chestnut cankers was found to increase at 11 stations trending from the north to south, but to decrease with elevation at stations in the Catskills. Rainfall seems to bear no relation to canker development. The fungus can resume growth at once on return of atmospheric warmth. No relation of climatic factors to pycnospore development could be traced. Ascospores were not developed in some cases within 18 months after inoculation. No mature perithecia developed during 1914, but both perithecia and ascospores appeared abundantly at many stations in the (late) winter, spring, and summer of 1915, atmospheric moisture appearing to have considerable connection, temperature much less, with ascospore development. Perithecia were first observed in the spring during a period of high humidity in 1915. Dry weather apparently tends to reduce the spread of the chestnut blight by lessening spore production.

The results of the present investigation are said to agree with those reported by Rankin for Ulster County, N. Y. (E. S. R., 32, p. 54). The data here presented are thought to indicate a probability that chestnut canker will spread more rapidly in the Southern than in the Northern States.

The influence of temperature on the growth of Endothia parasitica, N. E. STEVENS (Amer. Jour. Bot., 4 (1917), No. 2, pp. 112-118, fig. 1).—The observations above noted have been continued, though abandoned at all but six stations on account of the increased prevalence of the disease, and the results are here tabulated and discussed.

The lateral growth of the cankers of *E. parasitica* on *Castanea dentata*, as noted at these stations for the year ending with May, 1916, as for the previous year, was apparently not influenced by the amount or frequency of rainfall. The rate of growth of the fungus agrees closely with the temperature for the period, as computed by the system of remainder summation indices, or that of exponential summation indices, and less closely but still in a general way with

that by physiological indices. It thus appears that temperatures is the chief climatic influence in determining the rate of growth of the chestnut-blight fungus.

Chestnut blight in West Virginia (W. Va. Dept. Agr. Bul. 18 (1916), pp. 110-112).—This is chiefly a discussion of information reported by Brooks as noted previously (E. S. R., 36, p. 150) and as supplemented by a later report. It is stated that late in May, 1916, the blight was found to be still spreading at the former rapid rate in the infected portions of West Virginia, but that by prompt and vigorous measures much could probably be done to check the disease in regions where infection is only sporadic and to keep it out of territory not yet infected.

Pycnia of Cronartium pyriforme, J. S. Boyce (Phytopathology, 6 (1916), No. 6, pp. 446, 447).—The author reports having observed on seedlings and small saplings of the western yellow pine (Pinus ponderosa) typical spindle-shaped or fusiform swellings on the main stem which contained innumerable pycnospores. It is believed that the pines are probably infected in the summer or fall of one season, the pycnia not appearing until the summer of the next season at the earliest, while mature æcia are produced in the late spring or early summer of the third season.

The white pine blister rust in Canada, W. A. McCubbin (Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 8 (1915-16), pp. 64-72, figs. 3).—While in both the United States and Canada numerous cases of white pine blister rust (Peridermium strobi) have appeared on pines imported from Europe, only one region in Ontario is known where the disease has attacked native white pines of considerable size. The degree of infection on that small area, however, suggests that this fungus might prove to be a very dangerous pest if it once obtains a foothold. Only five-leaved pines are known to be attacked. The main area affected (with the alternate stage on practically all species of Ribes but particularly on black currant) lies north of Lake Ontario, between Niagara Falls and Hamilton, with isolated areas in other localities which are named.

Experiments seem to show that the spread of the blister-rust fungus can be reduced by spraying currant bushes, but not entirely prevented by this indirect means.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

The Wyoming ground squirrel in Colorado with suggestions for control, W. L. Burnett (Off. State Ent. Colo. Circ. 20 (1916), pp. 11, pl. 1, figs. 2).—This account of the Wyoming ground squirrel (Citellus elegans) deals particularly with its distribution by counties and methods of control. The author states that from an agricultural standpoint it is the worst mammalian pest that has to be contended with in Colorado.

Destroying rodent pests on the farm, D. E. LANTZ (U. S. Dept. Agr. Yearbook 1916, pp. 381-398, pls. 5, fig. 1).—Means for destroying rodent pests are described.

Bird life in Washington, JENNIE V. GETTY (Seattle, Wash.: Lowman & Hanford Co., 1916, pp. 8+134, pl. 1, figs. 61).—A popular work dealing with the birds of Washington State, their songs, and nesting habits.

Observations on polycystid gregarines from Arthropoda, MINNIE E. WATSON (Jour. Parasitology, 3 (1916), No. 2, pp. 65-75, pl. 1).—A new genus, Bulbocephalus, with two new species, are described for the family Stylocephalidæ. New species are described for Pyxinia and Gregarina, and new data are given for gregarines already known.

On a trematode larva encysted in a crab, Helice tridens, S. Yoshida (Jour. Parasitology, 3 (1916), No. 2, pp. 76-81, figs. 2).—This paper relates to a

trematode the larva of which was found to infest a crab (*H. tridens*) in Japan. Of some 250 specimens of crabs examined 90 per cent were found to be infested with cysts of this parasite. Though this crab is not used as food in Japan proper, it is said to be eaten in some parts of Korea and Formosa.

The death-feigning instinct, E. M. DuPorte (Canad. Ent., 49 (1917), No. 7, pp. 221-225).—The author concludes that there is no consciousness involved in the death feint and that the instinct is merely a physicochemical reaction to external stimulus. "The most probable theory is that in the death feint we have an example of negative thigmotaxis, that shrinking from contact characteristic of so large a proportion of all classes of animals."

Arsenic as an insecticide, A. L. Lovett and R. H. Robinson (*Jour. Econ. Ent.*, 10 (1917), No. 3, pp. 345-349).—A brief report of experiments conducted in which lampblack and fullers' earth were used as adsorbents of arsenic from a water solution of arsenic acid.

It was found that under field conditions lampblack is not practical as the black color probably absorbs heat and increases the burn. Fullers' earth used as an adsorbent gave comparatively little burn. The results, based on a single season's observations, both as to toxicity for insects and as to amount of burn on apple foliage, indicate that there are possibilities in the use of adsorbents with arsenic.

Toxicity of various benzene derivatives to insects, W. Moore (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 11, pp. 371-381, pls. 2, figs. 2).—In continuation of fumigation work for the destruction of external parasites, previously reported (E. S. R., 35, p. 656), the author reports upon a series of 28 benzene derivatives. The results obtained, at the University of Minnesota, are summarized as follows:

"All the benzene derivatives tested proved to be more toxic to insects, molecule for molecule, than carbon bisulphid. Physical characters, such as boiling point and vapor pressure, have more influence on the toxicity than chemical composition. Up to 250° C. the higher the boiling point the more toxic the compound to insects. Beyond 250° the compound is usually so slightly volatile that not enough of the chemical will evaporate to be effective. Lipoids are very soluble in compounds with low boiling points and but slightly soluble in compounds with high boiling points. Compounds with low boiling points, although less toxic, owing to their great volatility may give better results than compounds with high boiling points, particularly in the fumigation of grain."

Carbon disulphid as an insecticide, W. E. Hinds (U. S. Dept. Agr., Farmers' Bul. 799 (1917), pp. 21).—This is a revision of Farmers' Bulletin 145, previously noted (E. S. R., 13, p. 971).

Nicotin sulphate as a poison for insects, A. L. Lovett (Jour. Econ. Ent., 10 (1917), No. 3, pp. 333-337).—The author's experiments with Malacosoma pluvialis indicate that nicotin sulphate is a very powerful repellent for caterpillars. Where feeding does take place, the action of the nicotin is apparently rapid and sure, even small bits of foliage sprayed with comparatively weak solutions killing, when devoured, after a short time.

Tests of nicotin sulphate in the control of the codling moth made under unfavorable conditions are briefly considered.

The practical use of the insect enemies of injurious insects, L. O. HOWARD (U. S. Dept. Agr. Yearbook 1916, pp. 273-288, ftgs. 8).—A brief popular account in which attention is called to the benefits obtained from the use of insect parasites and predators. A technical account of some of the work has been previously noted (E. S. R., 25, p. 662).

Losses caused by imported tree and plant pests, C. L. MARLATT (Amer. Forestry, 23 (1917), No. 278, pp. 75-80, figs. 12).—A discussion of the losses re-

sulting from imported insect pests, presented at the International Forestry Conference of the American Forestry Association at Washington, D. C., in January, 1917. See also a previous note (E. S. R., 17, p. 159).

Notes on a southern trip, W. D. PIERCE (Proc. Ent. Soc. Wash., 18 (1916), No. 4, pp. 206, 207).—The author records observations of the collection of Lachnosterna, etc., by insect-catching plants (Sarracenia spp.) in southern Georgia; the mining of leaves of the bay (Magnolia virginiana) by Prionomerus calceatus; the feeding of the cowpea weevil on the terminal buds of cotton; and the infestation of the flat galls of Phylloxers carya-avellana by larvæ of Anthonomus hicoria.

Second biennial report of the Montana State Board of Entomology, R. A. Cooley (Bien. Rpt. Mont. Bd. Ent., 2 (1915-16), pp. 66, figs. 8).—Following a brief statement of the work of the year the following papers are presented: Report on the Investigation and Control of the Rocky Mountain Spotted Fever Tick in Montana during 1915-16, by W. V. King (pp. 13-23); Review of Rocky Mountain Spotted Fever Eradicative Work Conducted by the United States Public Health Service in the Bitter Root Valley, Mont., 1915-16, by L. D. Fricks (pp. 24-27); Rocky Mountain Spotted Fever.—A Report of Laboratory Investigations of the Virus, by L. D. Fricks (pp. 28-34), previously noted (E. S. R., 36, p. 158); The Etiology of Rocky Mountain Spotted Fever, by S. B. Wolbach (pp. 35-44); Some Facts of Importance Concerning the Rocky Mountain Spotted Fever Tick (Dermacentor venustus) in Eastern Montana, by R. R. Parker and R. W. Wells (pp. 45-56); and The House Fly and the Control of Flies, by R. R. Parker (pp. 57-66).

Annual report of the Government entomologist, C. C. Gowdey (Ann. Rpt. Dept. Agr. Uganda, 1916, pp. 48-53).—This report deals with the more important insect enemies of coffee, cacao, cotton, etc., for the year ended March 31, 1916.

Cotton pests in the arid and semiarid Southwest, A. W. MORRILL (Jour. Econ. Ent., 10 (1917), No. 3, pp. 307-317).—This is a summary of information on the cotton pests of the Southwest, including an annotated list of 23 references to the literature.

Some problems in insect control about abattoirs and packing houses, F. C. BISHOPP (Jour. Econ. Ent., 10 (1917), No. 2, pp. 269-277, pl. 1).—This report of studies made by the Bureau of Entomology in cooperation with the Bureau of Animal Industry of the U. S. Department of Agriculture discusses some of the special problems involved and the species of insects concerned.

Insects injurious to man and stock in Zanzibar, W. M. Aders (Bul. Ent. Research, 7 (1917), No. 4, pp. 391-401).—This consists largely of an annotated list of the more important insect and acarid pests of animals.

Guide to the specimens and enlarged models of insects and ticks exhibited in the central hall illustrating their importance in the spread of disease (Brit. Mus. (Nat. Hist.) Spec. Guide No. 7 (1916), pp. 45, figs. 14).—This is a special guide.

Methods of controlling grasshoppers, F. B. MILLIKEN (Kansas Sta. Bul. 215 (1916), pp. 5-30, figs. 19).—This is a report of control work with grasshoppers conducted during July, August, and September, 1911, with head-quarters at Dodge City, and during July and August, 1912, at Garden City, Kans.

It is concluded that most of the damage can be prevented if proper control measures are introduced into the regular farm practice. These control measures consist of the destruction of the eggs by plowing and disking, and of the destruction of the young and adults by the use of poultry and hogs, the hopperdozer, the poisoned bran mash, or by burning where there is sufficient vegetation to carry fire.

Grasshoppers and their control, H. C. Severin and G. I. Gilbertson (South Dakota Sta. Bul. 172 (1917), pp. 552-588, figs. 15).—This is a popular account of grasshoppers, which were unusually abundant in alfalfa fields in the greater part of South Dakota in 1916 (though the most severe attacks occurred in the western two-thirds of the State), and means for their control.

Destroy the grasshoppers, T. D. URBAHNS (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 7, pp. 249-253, figs. 4).—A popular account.

Report on the great invasion of locusts in Egypt in 1915 and the measures adopted to deal with it, A. T. McKillop and L. H. Gough (Cairo: Min. Agr., 1916, pp. X+72, pls. 14, figs. 2).—It is stated that in 1915 locusts appeared in the Nile Valley both from the west and from the east, as they apparently did the previous year. Driving the locusts into small trenches and burying them was found to be the best method of destruction under Egyptian conditions. Contact insecticides are useful but not to the same extent. Stomach poisons and Coccobacillus acridiorum were tested and found unsuitable for use in Egypt.

The several appendixes to this paper include Notes on the Migratory Locust (1904) (Acridium peregrinum), by W. Cartwright (E. S. R., 16, p. 485); a brief report on the cost of the locust campaign; etc.

New Thysanoptera from Florida, J. R. Watson (Ent. News, 26 (1915), No. 2, pp. 49-52, pl. 1; 27 (1916), No. 3, pp. 126-133, pls. 2).—The second paper, continuing previous work (E. S. R., 29, p. 354), includes descriptions of two species and one variety new to science. The third paper presents descriptions of three species and one subspecies new to science, and includes a key to the North American species of Aeolothrips, Anthrothrips, and Liothrips. None of the new forms is said to be of economic importance, although Aeolothrips floridensis n. sp. was taken from oats and Anthrothrips floridensis n. sp. from Indian corn, and Euthrips tritici projectus n. var. is a very common type in Florida in blossoms of orange, tomato, roses, begonia, etc.

An annotated list of the Thysanoptera of Plummer's Island, Md., J. D. Hoop (Insecutor Inscitiæ Menstruus, 5 (1917), No. 4-6, pp. 53-65).—The author records the collection of 57 species representing 18 genera in addition to several unidentified uniques from Plummer's Island, Md., in the Potomac River near the District of Columbia, and 17 additional species taken within a few miles of the island.

Two new species of Dicyphus from Porto Rico, E. H. Gibson (Canad. Ent., 49 (1917), No. 6, pp. 218, 219).—Two hemipterans Dicyphus prasinus and D. luridus, collected at Rio Piedras, P. R., where they are a source of injury to tobacco plants, are described as new.

The green bug (Toxoptera graminum) outbreak of 1916, E. O. G. Kelly (Jour. Econ. Ent., 10 (1917), No. 2, pp. 283-248).—This is a report of studies made of the outbreak of this pest in Kansas in the spring of 1916.

Plant lice injurious to apple orchards.—II, Studies on control of newly-hatched aphids, II, P. J. PARBOTT, H. E. HODGKISS, and F. H. LATHROP (New York State Sta. Bul. 431 (1917), pp. 33-79, pl. 1, figs. 4).—This report of life history studies and experiments with apple plant lice (Aphis sorbi, [A.] Sphocoryne avenæ, and A. pomi), conducted with a view to the establishment of efficient spraying practices for the protection of bearing apple orchards, is in continuation of that previously noted (E. S. R., 35, p. 757).

The more important results and applications from these efforts are dealt with under the headings of classification of newly-hatched larvæ and stem mothers of the first brood, seasonal behavior of aphids, influence of aphids on fruits, tests with lime-sulphur and nicotin solution, auxiliary experiments during 1916, the delayed dormant application in the spraying schedule, and a

plan for a spraying test. It is stated that, in general, infestation of orchards in western New York during 1916 was not severe. The oat aphis at the outset outnumbered the rosy aphis and the apple aphis in most orchards, although their comparative numbers varied locally. In relative abundance the three species exhibit a seasonal succession or cycle, which, while probably varying somewhat from year to year, appears to be fundamentally constant.

"At Geneva activities began with the hatching of goodly numbers of the oat aphis on April 22. A few rosy aphids were detected on the buds at the same date, but this species did not reach maximum numbers until four days later. The green aphis was the last species to hatch and began to emerge on April 26. As during the preceding year, dwarfing of apples was chiefly the work of the rosy aphis, although losses in fruit yields in this respect were rarely of serious extent.

"In experiments with the aphids all species attacked succulent tissues, as blossom and fruit stems, tender leaves, and young apples. As a result of their activities various distortions of apples developed. Severe infestation by A. sorbi and A. pomi was attended in a number of instances by destruction of entire clusters of apples.

"In an experiment on Rome apples an application on May 1 of lime-sulphur and nicotin sulphate at recommended strengths afforded efficient protection from the oat aphis and the rosy aphis. The trees receiving the treatment were also free from the green aphis until June, when there was a reinfestation of the plat due to invasion by winged migrants. Of 12 auxiliary experiments, 9 gave appreciable benefits from spraying. The remainder were inconclusive because of slight infestation by the insects or excessive defoliation by apple scab assisted in part by aphids."

The reddish-brown plum aphis (Rhopalosiphum nympheæ), W. M. Davidson (Jour. Econ. Ent., 10 (1917), No. 3, pp. 350-353, fig. 1).—A report of observations made in California, where R. nympheæ is distributed in many of the plum and prune districts. It is generally confined to a few trees in an orchard and occasionally infests apricots and almonds; in the East it occasionally attacks peaches. Though apparently of European origin and recorded from many parts of Europe, it is known to occur from Maine to Virginia and in the Central States and Colorado, as well as Ontario and Japan.

Brief notes are given on its biology and habits and recognition characters, including comparative measurements. It is of especial interest in that it is double-hosted, spending the winter and spring on fruit trees and the summer and early fall on a large variety of water plants.

A paper on this pest by Patch has been noted (E. S. R., 34, p. 550).

The migratory habits of Myzus ribis, C. P. Gillette and L. C. Brage (Jour. Econ. Ent., 10 (1917), No. 3, pp. 338-340, fig. 1).—It is pointed out that while this aphid has long been known to leave the currant bushes during the middle of the summer no one has definitely determined the alternate hosts. The authors have repeatedly transferred the migrants from Ribes to Stachys and Leonurus and the fall migrants from these plants to the currant and had them take well, and thus feel safe in announcing these two genera, at least, as summer hosts of M. ribis.

Little-known western plant lice, II, W. M. DAVIDSON (Jour. Econ. Ent., 10 (1917), No. 2, pp. 290-297. fig. 1).—These notes relate to Vacuna dryophila, which occurs on valley oak (Quercus lobata) at Walnut Creek, Cal.; Callipterinella annulata, which infests the foliage and shoots of imported birch (Betula alba) in California and has been reported from other States; Aphis neo-mexicana pacifica n. var., which curls the terminal leaves of red currant at Walnut Creek, Cal.; and Myzus ribifolii n. sp., which curls and blisters the

foliage of the wild flowering currant (Ribes glutinosum) near Walnut Creek, Cal.

Methods for the study of mealy bugs, G. F. Ferris (Jour. Econ. Ent., 10 (1917), No. 3, pp. 321-325).—The author recommends the staining of specimens with magenta red in order to accentuate the characters that are of especial importance in the identification of mealy bugs. He asserts that for satisfactory study of mealy bugs and their allies the use of properly stained preparations is not only desirable but is in fact necessary. The method has also proved eminently satisfactory for use with other coccids, especially diaspine scales, as reported by Stafford, certain aphids, particularly chermes and phylloxera, and with cecidomyiid larvæ.

Insect parasites and predators as adjuncts in the control of mealy bugs, H. S. SMITH (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 3-4, pp. 108-114, figs. 10).—This paper gives brief accounts of the more important predacious and parasitic insect enemies of mealy bugs in California.

Some comparisons of Coccus citricola and C. hesperidum, H. J. QUAYLE (Jour. Econ. Ent., 10 (1917), No. 3, pp. 373-376).—The author here points out some of the differences and also some of the similarities of these two scales, which are quite distinct.

A scale insect new to California, H. S. SMITH (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 7, p. 249).—The author records the infestation of a palmetto near Riverside by the palmetto scale (Comstockiella sabilis).

The Mediterranean fig scale (Lepidosaphes ficus), F. P. ROULLARD (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 7, pp. 246-248, figs. 4).—A brief account of L. ficus, a European scale pest which has been discovered in Fresno County, where investigations are being made with a view to eradicating it.

Two new species of lace bugs, O. Heidemann (Proc. Ent. Soc. Wash., 18 (1916), No. 4, pp. 217-219).—Leptophya distinguenda, which abounds on witch-hazel from early spring until late fall in the vicinity of Washington, D. C., and Acalypta grisea from Massachusetts, North Carolina, and Maryland are described as new.

Notes on Leptobyrsa rhododendri, E. L. DICKERSON (Jour. N. Y. Ent. Soc., 25 (1917), No. 2, pp. 105-112, pl. 1).—These notes relate to the biology of a lace bug, previously described under the name L. explanata (E. S. R., 21, p. 451), which has since been shown to be the same as the Old World form L. rhododendri (E. S. R., 36, p. 656).

Check list of the Lepidoptera of Boreal America, W. Barnes and J. Mc-Dunnough (Decatur, Ill.: Herald Press, 1917, pp. IX+392).—This comprises a list of 8,495 species of Lepidoptera from North America, a list of species omitted as European or foreign, and a complete index (pp. 201-392).

The Barnes and McDunnough "list," H. G. Dyar (Insecutor Inscitiæ Menstruus, 5 (1917), No. 1-3, pp. 41-44).—This is a critical review of the above list. Suppression of the gipsy and brown-tail moths and its value to States

suppression of the gipsy and brown-tail moths and its value to States not infested, A. F. Burgess (U. S. Dept. Agr. Yearbook 1916, pp. 217-226, pls. 7).—A popular discussion of suppression work in which attention is called to the benefits resulting.

Solid stream spraying against the gipsy moth and the brown-tail moth in New England, L. H. Worthley (U. S. Dept. Agr. Bul. 480 (1917), pp. 15, pls. 16).—The methods of spraying and the apparatus developed during the course of work with the gipsy and brown-tail moths in New England are described and illustrated.

Louisiana records of the bindweed prominent (Schizura ipomeæ), E. S. Tucker (Canad. Ent., 49 (1917), No. 8, pp. 280, 281).—Observations of the occurrence and food habits of this lepidopteran in Louisiana are recorded.

Nepticulidæ of North America, Annette F. Braun (Trans. Amer. Ent. Soc., 43 (1917), No. 2, pp. 155-209, pls. 4).—In this synopsis of the family which includes the smallest species of Lepidoptera, the author recognizes 4 genera and 61 species (8 new), of which 54 belong to the genus Nepticula, 5 to Ectoedemia, 1 to Obrussa, and 1 to Glaucolepis n. g. With the exception of several gallmaking species of Ectoedemia, the larvæ of all species of which the life histories are known are miners within the tissues of leaves or in bark, but rarely in fruit. They show a preference for trees and shrubs, but not a few mine leaves of herbaceous plants, when full grown, the larva, with a few exceptions, leaves of herbaceous plants. When full grown, the larva, with a few exceptions, amongst the rubbish or in the loose surface soil. The species of Ectoedemia are gall producers or bark miners in forest trees. A list of their food plants and descriptions of mines occurring on them, compiled as an aid in identification, is included.

The pink bollworm, Pectinophora gossypiella, A. Busck (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 10, pp. 343-370, pls. 6, figs. 7).—This is a summary of the present status of knowledge of the pink bollworm, (Gelechia) Pectinophora gossypiella. This is based upon a review of the literature and investigations conducted by the author, the biological part of which was made in the Hawaiian Islands, where the cultivation of cotton has been abandoned on account of its injury.

The new genus Pectinophora is erected by the author for this species. It is pointed out that even a fraction of the insect in any of its stages can be recognized under the microscope by the characters given in this paper.

The paper includes (pp. 362-366) a similar detailed descriptive and anatomical account of another lepidopterous insect (*Pyroderccs rileyi*), known as the "scavenger bollworm," since it frequently occurs in decayed or dried bolls injured by other insects. This frequently has been and may be mistaken for the pink bollworm, but the anatomical details given in this paper make it possible for the inspector to distinguish readily these two insects.

A bibliography of 48 titles is included.

[New Lepidoptera], H. G. Dyar (Insecutor Inscitiæ Menstruus, 5 (1917), Nos. 1-3, pp. 8-10, 45-47, 50, 51; 4-6, pp. 65-92).—Several papers are here presented, all of which include descriptions of species new to science, namely, A Note on Cisthene (pp. 8-10); Three New North American Phycitinæ (pp. 45-47); A New Phycitid from the Bahamas (p. 50; A New Noctuid from Brazil (p. 51); Miscellaneous New American Lepidoptera (pp. 65-69); Notes on North American Pyraustinæ (pp. 69-75); Notes on North American Nymphulinæ (pp. 75-79); Notes on North American Schænobiinæ (pp. 79-84); Seven New Crambids from the United States (pp. 84-87); and Seven New Pyralids from British Guiana (pp. 88-92).

A county-wide survey to determine the effect of time of seeding and presence of volunteer wheat upon the extent of damage by the Hessian fly, T. H. Parks (Jour. Econ. Ent., 10 (1917), No. 2, pp. 249-253).—A report of investigations during the season of 1916, based upon a questionnaire and examinations of 306 fields in McPherson County, Kans.

The mosquitoes of the mountains of California, H. G. DYAR (Insecutor Inscitiæ Menstruus, 5 (1917), No. 1-3, pp. 11-21).—The author presents notes on all the mosquitoes found in the northern half of the Sierra Nevada Mountains of California, of which six species are described as new.

Bromelicolous anopheles, H. G. DYAB and F. KNAB (Insecutor Inscition Menstruus, 5 (1917), No. 1-3, pp. 38-40).—These notes relate to four species of Anopheles, of which one, A. hylephilus, is described as new to science.

A State-wide malaria-mosquito survey of California, W. B. Herms (Jour. Econ. Ent., 1θ (1917), No. 3, pp. 359-370).—The author reports upon a systematic anopheline survey in California and discusses the object and method of the survey and the results obtained.

The rice fields as a factor in the control of malaria, S. B. FREEBORN (Jour. Econ. Ent., 10 (1917), No. 3, pp. 354-359).—A discussion of the relation of rice fields to the occurrence of Anopheles in the Sacramento and San Joaquin Valleys of California, where rice has been introduced and is being grown commercially and malaria is already endemic.

A plea and a plan for the eradication of malaria throughout the Western Hemisphere, F. L. Hoffman (Newark, N. J.: Prudential Press, 1917, pp. 65, figs. 4).—The several parts of this work on the eradication of malaria, particularly through the control of mosquitoes, consist of a plea for organized action, a plan for organized prevention and control, and some essential statistical considerations.

Notes on horse flies as a pest in southern Florida, T. E. SNYDER (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 4, pp. 208-210).—These notes relate particularly to species of Tabanus.

A synoptic revision of the Cuterebridæ, with synonymic notes and the description of one new species, C. H. T. Townsend (Insecutor Inscitiæ Menstruus, 5 (1917), No. 1-3, pp. 23-28).—This paper includes a description of Bogeria scudderi n. sp., the larva of which is a parasite in the larynx of the hog in Virginia and Tennessee.

The head and throat bots of American game animals, C. H. T. TOWNSEND (Jour. N. Y. Ent. Soc., 25 (1917), No. 2, pp. 98-105).—A review of the present status of information on the biology of œstrids of the genus Cephenemyia.

"The flies of this genus larviposit at the entrance of the nostrils or on or about the nose or mouth of various members of the Cervidæ, and probably at times of certain allied families of ruminants. The newly deposited larvæ gain entrance to the host normally through the nostrils, but no doubt also at times through the mouth. They cling by their spines and mouth hooks to the mucous membranes near the point of entrance, and feed upon the mucous exudation which their irritation causes the membranes to secrete. On reaching the second stage they penetrate farther within."

Notes on Osten Sacken's group "Pæcilanthrax," with descriptions of new species, F. R. Cole (Jour. N. Y. Ent. Soc., 25 (1917), No. 1, pp. 67-80, pls. 5).—Four species of Anthrax and one variety are described as new.

The occurrence of Eumerus strigatus in Canada, A. Gibson (Canad. Ent., 49 (1917), No. 6, pp. 190, 191).—This relates briefly to the occurrence and distribution of this European dipteran in North America.

The Mediterranean fruit fly, E. A. BACK (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 3-4, pp. 69-80, pls. 2, figs. 5).—A summary of information relating to Ceratitis capitata, including colored plates which illustrate its infestation of peaches and citrus fruits. Reports of studies of this pest by the author and Pemberton have been prevously noted (E. S. R., 35, pp. 362, 760).

Mediterranean fruit fly (Ceratitis capitata) breeds in bananas, H. H. P. Severin (Jour. Econ. Ent., 10 (1917), No. 3, pp. 318-321).—In referring to the paper by Back and Pemberton, previously noted (E. S. R., 34, p. 655), the author presents evidence in addition to that given in the previous paper (E. S. R., 29, p. 54), which supports the view that C. capitata may breed in bananas.

Dark currant fruit fly in California, Rhagoletis ribicola, H. H. P. SEVERIN (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 7, pp. 258-260. fig. 1).—The collection in California of a specimen of the dark currant fly (R. ribicola), which has been reported by Piper and Doane (E. S. R., 10, p. 869) to be of considerable economic importance in the State of Washington, is recorded.

The melon fly in Hawaii, E. A. Back and C. E. Pemberton (U. S. Dept. Agr. Bul. 491 (1917), pp. 64, pls. 24, figs. 10).—This is a summary of the present status of the knowledge of (Dacus) Bactrocera cucurbitæ, based upon a review of the literature and the authors' investigations conducted during a period of several years; and including the studies previously noted (E. S. R., 32, p. 452).

An annotated bibliography of 51 titles is appended.

The root maggot pest, E. B. Stockey (Washington Sta., West. Wash. Sta. Mo. Bul., 5 (1917), No. 3, pp. 32-34, figs. 4).—The root maggot is said to be very common throughout western Washington and to do considerable damage each year to various cruciferous plants and also to onions. The work of the year was largely in connection with the kale crop. Previous experiments indicate "that to use fall-seeded kale for early transplanting in the spring is a good practice, both from the standpoint of size and freedom from root maggot; that transplanted plants should be protected by tarred felt pads; and that the later seedings and transplantings are usually less damaged by root maggot than those from early spring seeding.

"The average loss the past year on transplanted kale protected by tarred felt pads varied from 8.65 to 12.1 per cent, as against averages of 28.36 to 45.9 per cent loss where no pads were used. The average loss from transplanted fall-seeded plants was 28.36 per cent, as against an average loss of 33.7 per cent for transplants from spring seeding. The average loss from kale seeded in the field May 8 and thinned June 20 amounted to 11.2 per cent, as against 21.5 per cent from spring-seeded plants transplanted at the same time."

Notes on some western Buprestidæ, H. E. Burke (Jour. Econ. Ent., 10 (1917), No. 3, pp. 325-332).—The author notes the occurrence of, habits, and injury caused by 44 species of the flat-headed borers. A table for the separation of the various genera of borers and other data are given in a bulletin previously noted (E. S. R., 36, p. 554).

A new species of Agrilus from California, W. S. FISHER (Canad. Ent., 49 (1917), No. 8, pp. 287-289).—Under the name Agrilus burkei the author describes a new buprestid, the larvæ of which mine in the inner bark and wood of normal, injured, and dying white alder (Alnus rhombifolia) and paper-leaf alder (A. tenuifolia) at Placerville, Cal.

The locust borer (Cyllene robiniæ), C. E. SANBORN and H. R. PAINTER (Oklahoma Sta. Bul. 113 (1917), pp. 3-8, figs. 4).—A brief summary of information on this beetle, which is one of the most injurious pests of the locust tree in Oklahoma, where many of these trees are grown for posts as well as for shade. A bibliography of 24 titles is included.

Studies of this pest by Garman in Kentucky have previously been noted (E. S. R., 35, p. 552).

A new species of Xylotrechus, W. S. FISHER (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 4, pp. 214-216).—Xylotrechus aceris, a new cerambycid which makes galls on maple trees, is described from Washington, D. C. It also occurs in Pennsylvania, Delaware, and Kentucky.

The horse-radish flea-beetle: Its life history and distribution, F. H. CHITTENDEN and N. F. Howard (U. S. Dept. Agr. Bul. 535 (1917), pp. 16, figs. 6).— (Haltica) Phyllotreta armoraciæ, a European pest thought to have been introduced in horse-radish, having first been collected at Chicago in 1893, now occurs from New York and New Jersey to Quebec, Canada, and westward to

Nebraska. The injury is caused by the larvæ, which bore into the petioles or midribs of horse-radish ([Nasturtium] Radicula armoracia), and by the adults, which feed on the leaves, causing the characteristic flea-beetle injury—withering and dying—or gouge deep pits in the petioles or midribs. In 1914 it became of economic importance in the growing of horse-radish on a commercial scale in Brown County, Wis., and in the two years following reappeared in large numbers. It is also a source of injury at Shermerville, Ill., to the extent of thousands of dollars every year. This beetle is partial to horse-radish and marsh cress but has once been taken on young cabbage in hotbeds in early spring.

The species hibernates as an adult, appearing in its northern range in April and May. The eggs are deposited from the latter part of April or early May until early August, the crevices of the tender petioles of young leaves where they leave the root usually being the preferred location. A total of 418 eggs deposited at intervals in numbers of about 22 were recorded from a single female. The incubation period of the egg required from 7 to 14 days.

On hatching, the larvæ crawl about the leaf for some time, examination of a small tender petiole showing that they enter at different places along the inner side. The larvæ grow and feed in the tissues of the petioles and midribs of the leaves, and when very numerous the petioles are tunneled to the extent that they shrink considerably, causing the leaf to wither and die at the tip and about the margins.

When the larvæ are ready for pupation, they leave the petioles and enter the ground. That the larvæ may also live in the root of the plant is said to have been clearly demonstrated. After leaving the plant the larva enters the soil to a depth of from  $\frac{1}{2}$  to  $\frac{1}{2}$  in., or even 3 in., where it remains for 4 or 5 days, pupating in from 2 to 6 days. Forty-eight days was the total larval period of an individual which was deposited as an egg on May 1; others required periods of from 52 to 66 days and 10 to 13 days for pupal development.

The length of the oviposition period was found to be about 75 days, from the middle of May to the first of August. The total period of time from egg laying to adult ranges from 77 days to about 90 days in the cases where complete records were obtained. The adult appears to live about a year, there being but one generation annually in Wisconsin.

Bordeaux applied on the first appearance of the beetle is recommended as a preventive to be followed by arsenate of lead where necessary.

A bibliography of 10 titles is appended.

The two-banded fungus beetle, F. H. CHITTENDEN (Jour. Econ. Ent., 10 (1917), No. 2, pp. 282-287. fig. 1).—Alphitophagus bifasciatus, a cosmopolitan fungus beetle, is a scavenger usually found in refuse, such as decaying vegetable matter, in flour and feed stores, in mills, and in grain warehouses, and is not uncommon in the open as well as indoors. The present paper gives a brief summarized account of observations of the pest.

A troublesome household pest (Attagenus plebius) of Hawaii, J. F. Illingworth (Jour. Econ. Ent., 10 (1917), No. 3, pp. 340-344, fig. 1).—This dermestid, which has habits somewhat similar to the black carpet beetle (A. piceus) of the United States, is said to be an important household pest in the Hawaiian Islands, though apparently not found elsewhere. A note is given on its life history, together with technical descriptions of its several stages, and brief mention is made of control measures. A second fumigation with carbon bisulphid is necessary, as the eggs are not thus destroyed.

Studies on the life history of Ligyrus gibbosus, W. P. Hayes (Jour. Econ. Ent., 10 (1917). No. 2, pp. 253-261. pl. 1).—L. gibbosus, which first came into prominence as an enemy of the wild sunflower, is growing in importance as a

pest of staple crops, among which are carrots, sugar beets, sugar cane, corn, cotton, celery, etc. In the present paper the author first gives a brief review of the present status of knowledge of the species, with references to the literature, and then reports upon studies made at the Kansas Experiment Station.

The adults are present in the soil throughout the winter and early spring. During the latter part of April, or the first few days of May, and continuing throughout the summer, they emerge at night and fly to lights, returning to the soil before daybreak. During the summer of 1916, eggs were plentiful at Manhattan from the last of May to late in July. Larvæ were present from June throughout the remainder of the summer and early fall, and pupæ from the last of July to the last of October. Thus far no satisfactory method of control has been worked out. No special time can be set for the destruction of the pupæ by plowing due to the fact that pupation extends over a long period.

Notes on an introduced weevil (Ceutorhynchus marginatus), J. A. Hyslop (Jour. Econ. Ent., 10 (1917), No. 2, pp. 278-282, fig. 1).—This European weevil (C. marginatus) was found by the author to infest nearly every seed head of the dandelion at Bridgeport, N. Y., in 1916.

The strawberry root weevil in British Columbia, R. C. TREHERNE (Canad. Ent., 49 (1917), No. 8, pp. 257-260).—The data here presented supplement those given in a bulletin previously noted (E. S. R., 32, p. 556).

[The rice water weevil], F. C. Quereau (Louisiana Stas. Rpt. 1916, pp. 25, 26).—Oil experiments with Lissorhoptrus simplex indicate that the application of 15 gal. per acre will result in a 25 to 40 per cent increase in yield. It is stated that 40 gal. of crude oil has been used to a single acre without injury to rice when the leaves were not resting on the surface of the water. By draining the land and allowing it to become dry 15 days after the initial irrigation the damage from the "maggot" is largely prevented.

A newly-introduced clover beetle (Sitones hispidulus), E. C. VAN DYKE (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 7, pp. 248, 249).—The author records the occurrence of this European clover beetle in California for the first time.

The A B C and X Y Z of bee culture, A. I. and E. R. Root (Medina, Ohio: The A. I. Root Co., 1917, rev. and enl. ed., pp. 8+830, pl. 1, figs. 732).—A new revised and enlarged edition of the work previously noted (E. S. R., 19, p. 1058).

Diprion simile in North America, S. A. Rohwer (Proc. Ent. Soc. Wash., 18 (1916). No. 4, pp. 213, 214).—The European pine sawfly D. simile, previously reported by Britton as occurring in several localities in Connecticut (E. S. R., 35, p. 53), is said to have been received from inspectors in Massachusetts, Pennsylvania, and New Jersey, though it is not known to have become established in any of these three States. It has, however, been received from one nursery in New York under conditions which indicate that it has become established.

The Argentine ant as an orchard pest, H. S. SMITH (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 7, pp. 254-258, figs. 3).—This ant has become an important orchard pest in California through its protection of mealy bugs and scale insects from their natural enemies. In investigations thus far poisoned sirup, placed in paraffin paper bags attached to trees, has given more promising results than banding.

Ants protecting acacia trees in Central America, E. A. Schwarz (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 4, pp. 211, 212).—Observations by the author in the Canal Zone of Panama and at Tampico, Mex., fully corroborate the original observations of T. Belt to the effect that the ants effectually defend the acacia

<sup>&</sup>lt;sup>1</sup>The Naturalist in Nicaragua. London: Edward Bumpus, 1888, 2. ed., rev., pp. XXXII + 403.

trees against the attacks of man, cattle, and insects. No leaf-eating caterpillars, no aphids, and no coccids were seen on the trees, and no leaf-cutting ants ever defoliate them.

Notes on Trichogramma minutum, S. C. Habland (West Indian Bul., 15 (1915), No. 3, pp. 168-175).—The author's experiments with this important parasite indicate that it parasitizes the eggs of the sugar-cane borer, the bollworm, the fall army worm, Utetheisa ornatrix, Calpodes ethlius, and an unidentified cutworm. It is pointed out that other egg parasites confine themselves to one particular host. Experiments show that T. minutum will not parasitize the eggs of a nonlepidopterous insect nor of a spider. In every case T. minutum was a subsidiary parasite, as the number obtained in the field was always less than that of the other egg parasites of the same host. Work is being carried on with U. ornatrix, with a view to making use of it in the control of the sugar-cane borer through serving as a host for T. minutum.

A nearctic species of Dolichurus, S. A. Rohwer (Proc. Ent. Soc. Wash., 18 (1916), No. 4, pp. 212, 213).—Dolichurus greenei n. sp. is described from Falls Church, Va.

On the life history and successful introduction into the United States of the Sicilian mealy bug parasite, H. S. SMITH (Jour. Econ. Ent., 10 (1917), No. 2, pp. 262-268, pls. 2, figs. 5).—This paper relates to the Italian encyrtid parasite of mealy bugs, described by Girault as Paraleptomastix abnormis (E. S. R., 34, p. 456), accounts of which have previously been noted (E. S. R., 34, p. 451).

Reproduction took place so rapidly that before many months large colonies were placed in the orchards of southern California. The parasite is now quite thoroughly distributed throughout the mealy-bug infested sections of the State and has become established in practically every colony. In many of the orchards under investigation it has successfully passed through two fumigations, probably as larvæ and pupæ within the young mealy bugs. Spraying does not destroy it, except where it is successful in killing the mealy bugs. While it will occasionally deposit eggs in *Pseudococcus bakeri*, the author has never succeeded in rearing it from this host. In work in Hawaii Swezey has succeeded in getting it to breed upon *P. sacchari*, though it does not thrive greatly on that species.

Some new Australian chalcid flies, mostly of the family Encyrtidæ, A. A. GIRAULT (Insecutor Inscitiæ Menstruus, 5 (1917), No. 1-3 pp. 29-37).

New Australian chalcid flies, A. A. GIRAULT (Insecutor Inscitiæ Menstruus, 5 (1917), No. 4-6, pp. 92-96).—The author erects a new genus (Paramyiocnema) and describes six species as new to science.

A chalcid parasite of the pink bollworm, A. A. GIBAULT (Insecutor Inscitive Menstruus, 5 (1917), No. 1-3, pp. 5, 6).—Under the name Stomatoceras pertorvus, the author describes a parasite reared from pupe of (Gelechia) Pectinophora gossypiella at Honolulu, Hawaii, which has previously been referred to as Hockeria sp.

Two bethylid parasites of the pink bollworm, S. A. Rohwer (Insecutor Inscitiæ Menstruus, 5 (1917), No. 1-3, pp. 1-3).—Perisierola nigrifemur Ashm. is recorded as parasitic on the larvæ of the pink bollworm (Gelechia) Pectinophora gossypiella in Brazil. P. emigrata, which has been reared in great numbers from the larva of the pink bollworm in Honolulu, Hawaii, is here described as new. Specimens from Texas referred to under the name P. distinguenda and recorded as parasites of Bruchus prosopidis and Bruchus sp. are considered to be P. emigrata.

16179°-17-No. 6-6

The occurrence of the genus Parachrysocharis in the United States, A. A. GIRAULT (Canad. Ent., 49 (1917), No. 4, p. 129).—A new species, based on specimens collected at Austin, Tex., is here described as Parachrysocharis semiflava.

Two apple leaf mites of economic importance, W. H. BRITTAIN (Canad. Ent., 49 (1917), No. 6, pp. 185-189, pl. 1).—This article deals with the silver-leaf or rusty leaf mite (Phyllocoptes schlechtendali), which is extraordinarily abundant in the Okanogan Valley and other parts of the dry belt of British Columbia, and the apple leaf mite (Eriophyes malifoli $\alpha$ ), which, though it has not appeared in destructive outbreaks, may yet prove of greater economic importance than is commonly supposed, at least under conditions that exist in the Okanogan.

### FOODS-HUMAN NUTRITION.

Goat's milk as food for infants and very young children, W. H. JORDAN and G. A. SMITH (New York State Sta. Bul. 429 (1917), pp. 12-20).—This is a reprint of a report of a practical study of goat's milk in infant feeding when compared to cow's milk, by D. H. Sherman and H. R. Lohnes (E. S. R., 32, p. 66), together with reports of results obtained with 16 children as reported by parents or physicians.

Milling properties of Ohio wheat.—Differences in physical characteristics and milling qualities, Mabel K. Corbould (Mo. Bul. Ohio Sta., 2 (1917), No. 6, pp. 188-192, fig. 1).—This reports the methods used in determining the physical and milling characteristics of wheat and gives the score card and milling record of several samples of Ohio wheats. The experiments showed the following results:

"The Poole and Fultz wheats and their pure line selections (Ohio 9,920, Portage and Trumbull) have good milling qualities and make good flour. The Mediterranean, a good milling wheat, and its selection (Ohio 9,700) give a creamy flour. Early Ripe flour is a dirty gray, a very objectionable characteristic. The Gypsy mills well and makes a satisfactory flour. Gladden flour excels Gypsy, from which it was originally selected, in baking qualities. Dawson Golden Chaff gives a large percentage of bran, and a very white, starchy flour. Mealy produces a very deep cream flour, granular to the touch, due to poor milling qualities."

The value of sugar and honey as foods, E. PERUCCI (Agr. Mod. [Milan], 28 (1917). No. 4, pp. 41-43).—The food values of honey and sugar are compared and analyses of nectar and honey are given. The author claims that honey contains radium in addition to other salts.

Miscellaneous drug preparations, C. D. Woods (Maine Sta. Off. Insp. 82 (1917), pp. 29-36).—Results of analyses of samples of nitrous ether, spirit of peppermint, tincture of iodin, and spirit of camphor are reported.

[Food and drug inspection], E. F. Ladd and Alma K. Johnson (North Dakota Sta. Spec. Bul., 4 (1917), No. 13, pp. 347-362).—This contains the results of analyses of several samples of beer and general information regarding a number of drugs and patent medicines, together with miscellaneous information on food and drug topics.

Preliminary report of the dairy and food commissioner for the year 1916, J. Foust (*Penn. Dept. Agr. Bul. 292* (1917), pp. 53).—This is a preliminary report which reviews the work of the food inspection department during the year ended December 31, 1916.

Food and drug laws of the State of Rhode Island (Providence: E. L. Freeman Co., 1917, pp. 32).—The texts of the laws and the rules and regulations for their enforcement are given.

What to eat in war time, G. Lusk (World's Work, 34 (1917), No. 4, pp. 446-452).—A more or less popular statement of the food needs of the body, together with information regarding food costs and some plans adopted to meet the shortage of food in Europe.

Food economy in war time, T. B. Wood and F. G. Hopkins (London: Cambridge University Press, 1916, pp. 35).—This bulletin deals with the uses of food, food values, and food costs.

Food values and the rationing of a country, R. SMITH (London: Author, [1917], 2. ed., rev., pp. 19).—This publication considers the question of food supply and food regulation in the light of war conditions. Tables are included which show the composition of different foods and various so-called standard diets.

The restricted supply of food: Its relation to health and efficiency, M. S. Pembrey (*Brit. Med. Jour., No. 2941, Epit. (1917), pp. 605-607*).—A summary and digest of data relative to the food requirements and standard diets, together with suggestions regarding the regulation of the food supply.

Contribution to the study of incomplete diets.—Researches on the gaseous exchange of subjects receiving a rice diet, P. Ramoino (Arch. Ital. Biol., 65 (1916), No. 1, pp. 1-16).—Present-day theories regarding the etiology of polyneuritis are given and accounts of experiments made by the author are reported in detail. Four pigeons were fed upon a rice diet, and observations were made of the daily weight, the hourly consumption of oxygen per 100 gm., and the hourly production of carbon dioxid per 100 gm., as well as the respiratory quotient.

In general, it was found that pigeons maintained on the diet of polished rice died; this being in agreement with the results of other workers. The administration of the polishings or the extracts of rice bran served to retard or even to prevent the appearance of the symptoms, and this substance was active even in extremely small quantities. Discontinuing this administration caused a reduction of weight and the appearance, after a short interval, of the symptoms.

The study of the respiratory exchange showed in a like manner a progressive and rapid lowering of the respiratory quotient in passing from a diet rich in vitamins to a diet deprived of them. This lowering was due to the fact that the quantity of oxygen consumed did not follow a descending curve parallel to that of the carbon dioxid emitted.

The value of the respiratory quotient increased promptly to normal when the polishings were administered. After the administration of the polishings was discontinued the quotient again fell to an extremely low point.

The physiological behavior of raffinose, S. Kuriyama and L. B. Mendel (Jour. Biol. Chem., 31 (1917), No. 1, pp. 125-147, fig. 1).—From experiments with laboratory animals (rabbits and dogs) which are reported, the following conclusions in part were drawn:

Human saliva and the bile, pancreas, liver, and intestinal mucous membranes of laboratory animals did not contain raffinase. Under suitable conditions the gastric juice may invert raffinose. When raffinase and raffinose were injected successively into the circulation, the sugar was no better utilized than when it was injected alone.

"No noteworthy glycogen formation in the liver was found after feeding raffinose to fasting white rats. The sugar was scarcely inverted in the stomach and small intestine. It was, however, changed in the large intestine.

"When raffinose was administered directly into loops of the small intestine of [fasting] dogs, most of it was recovered after two hours without evidence of its inversion. In a loop of the large intestine, however, raffinose was easily

inverted. This was probably due to bacteria. Part of the raffinose can pass unchanged through the intestinal wall and reappear in the urine. . . .

"The sterilized feces of dogs and rabbits seems to contain a small amount of raffinase, probably of bacterial origin.

"Raffinose is devoid of food value until after its inversion. It may be that raffinose-digesting bacteria occur more frequently in the large intestine of species which consume foods containing raffinose and thus render the physiological utilization more probable for them."

A bibliography is appended.

## ANIMAL PRODUCTION.

The function of live stock in agriculture, G. M. ROMMEL (U. S. Dept. Agr. Yearbook 1916, pp. 467-475).—This paper which was read at a meeting of the Second Pan American Scientific Congress, Washington, D. C., has already been noted (E. S. R., 34, p. 305).

[Japanese cane for steers], A. P. Kerr (Louisiana Stas. Rpt. 1916, pp. 16, 17).—To determine the value of Japanese cane as a grazing crop 20 steers were grazed for 60 days during the fall and winter of 1915–16. The steers were practically maintained on this crop although the season was very cold and wet.

Progress in handling the wool clip: Development in the West, F. R. Marshall (U. S. Dept. Agr. Yearbook 1916, pp. 227-236, pls. 4, fig. 1).—An account is given of the more businesslike methods of handling the wool clip in the Western States during the past two seasons. In 1915 the wool growers began to grade their wools before shipment, and in 1916 about 7,000,000 lbs., including 81 clips and representing about 870,000 sheep in three far Western States, was graded and baled at the time of shearing. This wool when shipped was ready for final sale without the usual further handling undergone by most clips in the dealers' warehouses before sale to manufacturers.

Descriptions, with an illustration of floor plan, are given of shearing sheds which have been erected or remodeled to include the main features of the Australian plan. The author describes the principal methods used in preparing the clips in 1915–16 and discusses the advantages of grading at the ranch and the methods of selling ranch-graded wool. The new plan makes it possible for the flockmaster who studies his wool to appraise his clip closely when considering offers, but the full financial value of the system is not expected to be obtained until the growers have made a more general use of the system, thus securing wider competition for the purchase of their wools.

The adaptability of the plan to other States is pointed out, and examples of cooperative selling of wool in New York State and Louisiana are noted.

The production of pork in the four-year rotation, A. P. Kerr (Louisiana Stas. Rpt. 1916, p. 17).—In a four-year rotation of corn and cowpeas, soy beans, sweet potatoes, and mangels from 12 to 16 lbs. of pork were produced per bushel of corn, the amount depending a great deal on the crop of cowpeas in the corn. In this test from 2.5 to 3 bu. of sweet potatoes were equal in feeding value to 1 bu. of corn. The yields of soy beans have been very variable but the crop has proved a valuable one in the rotation as it is ready to graze between the corn and cowpeas and the sweet potatoes.

Stallion legislation and the horse-breeding industry, C. C. GLENN (U. S. Dept. Agr. Yearbook 1916, pp. 289-299, pls. 4, flg. 1).—The author notes that progress in horse breeding has not kept pace with that of many other agricultural lines. He attributes this condition largely to the too general use of stallions lacking in quality of breeding and to the failure on the part of owners of

mares to appreciate fully the value of sound pure-bred sires of desirable conformation. A brief review is made of the requirements and effects of laws regulating the public service of stallions and jacks in the various States. The first of these laws was that of Wisconsin which became effective on January 1, 1906, since when 20 additional States have enacted legislation of similar character.

Latest available statistics from 18 of these States are tabulated. Of the 55,553 stallions licensed for public service in these States 59 per cent are purebred, 33 grade, and 8 cross-bred and mongrel. It is noted that since the beginning of stallion legislation in these States there has been a general increase in pure-bred stallions and a decrease of grades and mongrels.

A list is given of the various State stallion registration boards or commissions.

The poultryman's problems in 1917, H. R. Lewis (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 9, pp. 4).—The importance of the production of infertile eggs for market is emphasized and suggestions are given for the systematic culling of layers, compounding war-time rations, and caponizing.

The Thanksgiving turkey, A. S. Weiant (U. S. Dept. Agr. Yearbook 1916, pp. 411-419, pls. 3).—This is a brief review of the market turkey industry in this country, including methods of raising, marketing, killing and dressing, and shipping.

Fur farming as a side line, N. Dearborn (U. S. Dept. Agr. Yearbook 1916, pp. 489-506, pls. 2).—It is stated that the solution of the problem of obtaining from a waning source the necessary stock for the permanent development of the fur industry is to "domesticate the fur bearers and farm them, as has been done over and over with other animals. The killing pressure on those remaining in the wild state will then be reduced, the fur trade supported, and a new farm product developed." Of about a dozen kinds of fur-bearing animals native to North America which are considered to be suitable for domestication, the skunk, mink, and silver fox have already been bred successfully in captivity in widely scattered localities, and the marten, fisher, otter, blue fox, raccoon, and beaver have been partially tested under domesticated conditions.

The habits and climatic conditions suitable for the raising of fur-bearing anicals are noted, and directions are given for the choice of species, construction of inclosures, feeding, breeding, treatment of diseases, care of skins, and the dressing of furs. The cooperation of breeders of fur-bearing animals is strongly urged.

A critique of the theory of evolution, T. H. Morgan (*Princeton: Princeton University Press, 1916, pp.* X+197, figs. 95).—This is a series of lectures delivered at Princeton University, in which the author (1) attempts to put a new valuation on the traditional evidence for evolution, (2) deals with the most recent work on heredity, (3) examines in the light of new observations the physical basis of heredity and the composition of the germ plasm stream, and (4) develops the thesis that chance variation, combined with a property of living things to manifold themselves is the keynote of modern evolutionary thought.

## DAIRY FARMING-DAIRYING.

An experiment in community dairying, R. R. Welch (U. S. Dept. Agr. Yearbook 1916, pp. 209-216, pl. 1, fig. 1).—An account is given of an experiment conducted by the Dairy Division in developing community dairying at Algona, Iowa, in a region where most of the farmers were engaged in grain farming and stock raising, dairying being only a side line. During the five years of the

experiment the project was constantly in charge of a field man who worked among the farmers and was assisted by the butter maker at the Algona creamery.

For the five years it is estimated that, as a result of the experiment, the net profits to the creamery patrons from larger and more economical production of milk fat and better quality of butter manufactured were increased by \$20,973. The effects of the work were also shown in the organization of a county butter makers' association, a cow-testing association, a Holstein breeders' association, and various other activities looking to the betterment of dairying in the region.

The author believes that community development in dairying can be carried on with advantage in close cooperation with, and perhaps under the direction of, county agricultural agents.

The cow makes farming more profitable, compiled and edited by P. G. HOLDEN and C. M. CARBOLL (Chicago: International Harvester Company of New Jersey, 1917, pp. 122 figs. 84).—This manual is a compilation of brief articles on the care and management of dairy cattle and the production and sale of milk and butter.

Beginnings of the dual-purpose Shorthorn type, W. Graham (Breeder's Gaz., 71 (1917), No. 25, pp. 1235, 1236, fig. 1).—In this article the author reviews the rise of Shorthorn cattle-breeding interests in Cumberland and Westmoreland Counties, England. The data are taken for the most part from original catalogues of sales.

Cooperative bull associations, J. G. WINKJER (U. S. Dept. Agr. Yearbook 1916, pp. 311-319, pls. 3, fig. 1).—A brief review is given of the activities of this Department and the State agricultural colleges in the formation of cooperative bull associations and of the advantages arising from such associations.

The first of these associations in the United States was formed in Michigan in 1908. In 1916 there were 32 active associations in this country, with a membership of 650, owning about 120 pure-bred bulls.

Cooperative bull associations which are formed by farmers for the joint ownership, use, and exchange of high-class pure-bred bulls have been found especially adapted to small herds where a valuable bull for each herd is too large an investment. Among the advantages noted are better and fewer bulls, low cost per member, quick returns on investment, opportunity for more intelligent breeding, elimination of the scrub, encouragement of community breeding, and improvement of herd production due to the use of good sires.

[Dairy herd records] (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 42 (1916), pp. 24-26).—Tabular data show in detail for each of 34 pure-bred cows of the Macdonald College herd the amount and cost of feed consumed, cost of pasturage, amount and value of milk and fat produced, profit, and cost of production of milk and fat.

The highest record of the year was made by the 5-year-old Holstein cow, Young Springwood. This cow produced 20,110 lbs. of milk containing 821 lbs. of fat in one year, and returned a profit above cost of feed of \$188.57.

Pasturing cows v. stable feeding (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 42 (1916), pp. 26, 27).—A comparison was made of the performance of nine cows fed during the year exclusively in the stable but allowed outdoor exercise in a moderate sized yard, and of nine other cows from the college herd pastured during the summer.

The cows fed in the stable showed an average annual record of 14,048 lbs. of milk and 528 lbs. of fat, and produced a profit of \$89.35 from \$119.04 worth of feed. Those pastured showed an average annual record of 12,361 lbs. of

milk and 468 lbs. of fat, and produced a profit of \$95.38 from \$86.26 worth of feed and pasture.

Cost of milk production (Mo. Bul. Ohio Sta., 2 (1917), No. 6, pp. 193-197).—A brief review is given of the work done by the station since 1907 in assisting dairy farmers of the State in keeping production records of their cows and in computing profits and losses. Complete and dependable cost data giving yearly records of from one to five years for a number of herds are briefly summarized. These indicate that for the period covered there was an average loss of \$1.95 per head for veal calves sold on the 26 farms on which one or more veal calves were sold annually. In 30 herds the average loss in raising heifer calves to one year of age was \$6.90 per calf, and the calves were raised at a profit in only 5 of these herds. The average total cost of raising calves was \$32.32 to one year of age and \$67.22 to two years of age. In 22 of the herds there was a loss of \$10.94 per head on heifers grown from one or two years of age and in eight herds there was a gain of \$1 per head.

Data extending from 1910 to 1916, inclusive, and covering 76 yearly herd records from 31 herds indicate that the labor cost per cow annually, at 15 cts, per hour for man labor and 8.2 cts. per hour for horse labor, was \$26.55. The feed cost per cow annually ranged from \$35.33 to \$85.12, with an average of \$52.86. The total cost per cow ranged from \$73 to \$147 per year, with an average of \$102 per year. The herd average of annual milk production ranged from 4,329 to 9.400 lbs. per cow, with an average of 5,868 lbs. The cost per 100 lbs. of milk, including loss on young stock, ranged in the various herds from about \$1.50 to more than \$3, and the average was approximately \$1.90. The average cost per 100 lbs. of milk, less the loss on young stock, was about \$1.56.

Standard calf rearing chart (Irish Homestead, 24 (1917), No. 31, pp. 590, 591).—This chart shows the average weights, condition of teeth, and methods of feeding normal dairy calves by weeks to the age of 24 weeks. Brief directions are given for the use of the chart.

Goat's milk for infant feeding, W. H. JORDAN and G. A. SMITH (New York State Sta. Bul. 429 (1917), pp. 3-12, pls. 2).—Data are given on the amount of feed consumed and the quantity and composition of milk produced during the years 1910 to 1912, inclusive, by a herd of milch goats at the station. The flock consisted of some very good animals, including one pure-bred Saanen and several pure-bred Toggenbergs. The number of animals of which complete records were kept varied from 10 to 26. During 1912, 31 adults and 9 partially grown animals consumed \$441.95 worth of feed. The average cost per month per goat varied from 79.1 cts. to \$1, and per goat per year was \$11.05. The yearly production of milk, including some animals in the first period of lactation, varied from 301.7 to 1,845.2 lbs. The average yearly yield for 10 animals of which records were kept during three years, including 28 lactation periods, was 800.4 lbs. The feed cost of the milk per goat for all the goats during the year 1912 was 4 cts. per quart and for the three years during which the record was kept, 3.4 cts. The lowest cost was with the Saanen goat for the year 1911, which was estimated to be 1.27 cts. per quart.

The range of composition of the mixed milk of the whole flock as determined during May and June of the year 1912 was as follows: Solids, from 11.4 to 11.9 per cent; solids-not-fat, from 7.72 to 8.61 per cent; fat, from 3.5 to 3.8 per cent. The composition of milk from individual goats was found to vary in total solids from 9.22 to 18.55 per cent; in protein, from 2.24 to 4.96 per cent; in casein, from 1.56 to 4.6 per cent; in fat, from 1.08 to 8.4 per cent; and in ash, from 0.43 to 0.8 per cent.

A chemical study of the milk has already been noted (E. S. R., 34, p. 708).

Goat milk good for babies (New York State Sta. Bul. 429, popular ed. (1917), pp. 3-7, fig. 1).—A popular edițion of the bulletin noted above and on page 570.

Dairying (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 42 (1916), pp. 18-21).—A brief report is made of dairy investigations conducted during the year at Macdonald Agricultural College.

It was found practicable to make rennet at home or at the cheese factory where a supply of calves' stomachs is available. Pepsin in various forms was found to be a good substitute for rennet, but a mixture of pepsin and rennet is deemed preferable to the use of pepsin alone. It was not found economical to use less than the standard quantity of rennet (3 oz. to 1,000 lbs. of milk) in cheese manufacture even with rennet at the present high price. An increase of 5.6 lbs. of cheese per 1,000 lbs. of milk was obtained as a result of pasteurizing the milk. The use of 5 per cent lactic culture in pasteurized milk was found more satisfactory than the use of hydrochloric acid.

In experiments in operating hand cream separators, it was found that a reduction of 8 revolutions per minute below normal caused a decrease of about 3 per cent in the fat content of the cream, while an increase of 8 revolutions above normal caused an increase of about 3 per cent in the fat content of the cream. An increase in the temperature of the milk at the time of separating from 80 to 90° F, and from 90 to 100° had very little effect on results, except that the fat in the cream averaged about 1 per cent lower when separating at 100° as compared with separating at tempertures of from 80 to 90°. Variations of different depths of milk in the supply-tank of the separator from full to one-half and onequarter full, had very little effect on results, except that less than a full supply of milk in the supply can tended to reduce the capacity of the machine about 20 lbs. per hour. A variation from 3 to 4.1 in the percentage of fat in the milk separated had little effect, except that the milk containing the higher percentages of fat, averaging 3.8, produced cream testing an average of 31.3 per cent fat, while milk averaging 3.1 per cent fat, separated under similar conditions with 8 different types of machines, averaged 26.3 per cent fat in the cream. Rich, or high-testing milk, produces higher testing cream than low-testing milk.

Pasteurized sour cream showed a higher loss of fat in the buttermilk and a lessened yield of butter as compared with raw sour cream. These results emphasize the need of sweet cream for pasteurization for butter making.

Salt added to the drained butter in the churn at the rates of 4, 5, 7, and 8 oz. per 100 lbs. of butter produced finished butter containing 2, 2, 2.6, and 3.95 per cent of salt, respectively. This butter, made in June, was held in cold storage until September 28, when it was scored. The lot to which 8 per cent salt had been added was found to be "gritty," scored 42 out of 50 points for flavor, and a total of 87.5 points out of 100. The other lots were scored full for salt, and 44.5, 45, and 44, respectively, in flavor for the lots having 4, 5, and 7 per cent salt added, with total scores of 92.5, 92.5, and 92. The heavier salted lots were poorer in flavor after being held over three months in cold storage.

Skim milk cheese (Jour. Bd. Agr. [London], 24 (1917), No. 2, pp. 175-179).—A description is given of a method worked out by A. Todd, of the British Dairy Institute at Reading, for the manufacture of skim milk cheese from milk from which the cream is removed by hand-skimming or from separator skim milk to which enough whole milk is added to raise the fat content to about 1.5 per cent. Some of the essentials of the method are as follows:

The skim milk is raised to a temperature of 82° F., and when the acidity reaches about 0.19 per cent enough rennet is added to coagulate the milk in 35 minutes. When the curd has reached the proper consistency it is cut into ½-in. cubes, gently stirred by hand, and allowed to settle for 15 minutes.

The curd is then brought to 86°, with constant stirring, and allowed to settle for 30 minutes. It should then be firm and spongy and should readily sink to the bottom of the vat. When these conditions are obtained the whey should be poured off and the curd tied in cheesecloth and drained on a rack for about  $1\frac{1}{2}$  hours, the curd mass being cut into 4-in. cubes three or four times to facilitate drainage.

The curd is next broken up by hand and salt added at the rate of 1 oz. to 3 lbs. of curd. After a thorough stirring the curd is again inclosed in cheese-cloth and weighted in molds. After being pressed overnight the cheese is trimmed, bandaged in clean calico, again pressed for 2 hours, removed from the mold, placed in the making room, and turned daily for 2 or 3 days. It is then removed to a shelf in a cooling room and turned daily. The cheese is ready for use in from 3 to 5 weeks, and should keep in good condition for from 8 to 10 weeks. The yield is said to be about 3 lbs. of cheese for each 4 gal. of skim milk.

# VETERINARY MEDICINE.

The meat inspection service of the United States Department of Agriculture, G. Ditewig (U. S. Dept. Agr. Yearbook 1916, pp. 77-97, pls. 11, figs. 5).—This is a description of the manner in which the Federal meat inspection is carried out under the regulations previously noted (E. S. R., 32, p. 777).

Report of State veterinarian and State live stock sanitary board for 1914 and 1915, C. J. Marshall (Ann. Rpt. Penn. Dept. Agr., 21 (1915), pp. 89–173).—This report deals with the occurrence of and work with transmissible diseases of live stock in Pennsylvania, and includes an account of control work with foot-and-mouth disease, hog cholera, rabies, tuberculosis, etc.

Report of proceedings under the diseases of animals acts, with returns of the exports and imports of animals, for the year 1915, D. S. PRENTICE (Dept. Agr. and Tech. Instr. Ireland, Rpt. Diseases Anim., 1915, pp. 34).—This is the usual report (E. S. R., 35, p. 279) dealing with the occurrence of infectious diseases of animals, and including statistical data.

A further note on the life history of Gongylonema scutatum, B. H. RANSOM and M. C. Hall (Jour. Parasitology, 3 (1917), No. 4, pp. 177-181).—The questioning by Seurat, as previously noted (E. S. R., 37, p. 361) and elsewhere, of the identity of the species studied by the authors (E. S. R., 34, p. 783) has led to the further work here reported.

The authors have definitely proved that dung beetles and croton bugs fed upon the eggs of *G. scutatum* become infested with an encysted larval stage of the parasite. The evidence is also very strong, if not quite conclusive, that sheep, cattle, and other suitable mammalian hosts become infested as a result of swallowing infested insects which usually under natural conditions are various species of dung beetles.

"The nematodes found in several species of Blaps in Algeria and identified by Seurat as the larvæ of G. scutatum belong to some other species. It is not improbable that the nematodes found in Algerian beetles, which Seurat has considered to be the larvæ of G. mucronatum in reality belong to G. scutatum."

Spirochæta icterohæmorrhagiæ in American wild rats and its relation to the Japanese and European strains, H. Noguchi (Jour. Expt. Med., 25 (1917), No. 5, pp. 755-763).—"Wild rats captured in this country carry in their kidneys a spirochete which possesses the morphological and pathogenic properties characteristic of S. icterohæmorrhagiæ discovered by Inada in the Japanese

<sup>&</sup>lt;sup>1</sup> Compt. Rend. Soc. Biol. [Paris], 79 (1916), No. 14, pp. 717-742, figs. 5.

form of infectious jaundice. Cultures of the American, Belgian, and Japanese strains of the spirochete were obtained by special technique described, the first two strains having been cultivated artificially for the first time. Animals actively immunized against the Japanese strain resist inoculation, not only of the same strain, but also of the Belgian and American strains. The Belgian strain produces immunity equally effective against all three strains. Experiments to ascertain whether the immunity afforded by the American strain also protects against the Japanese and Belgian strains are in progress. These findings warrant the conclusion that the spirochetes designated here as the Japanese, Belgian, and American strains are probably identical.

"On account of its distinctive features a new genus, Leptospira, has been suggested as the designation of this organism."

The effects of radiation on the development of Trichinella spiralis, with respect to its application to the treatment of other parasitic diseases, E. E. Tyzzer and J. A. Honeij (Jour. Parasitology, 3 (1916), No. 2, pp. 43-56, pl. 1).—
"By radium radiation from the surface of the abdomen of the rat the injury of fully developed T. spiralis has not been accomplished. These worms appeared well developed and persisted longer than in controls. Similar treatment from the second day after the ingestion of cysts has apparently resulted in a retardation of development, 30 per cent of the females being immature. In a rat radiated in this manner from the time it was fed trichinous meat, only two immature worms were found seven days later, indicating that radiation of the larvæ before they have entered upon their period of development free in the intestine is fatal to them. . . .

"Observations on the life history of *T. spiralis* made in the course of these experiments indicate that certain points emphasized in books of reference do not apply to the development of this parasite in rats and mice. *T. spiralis* is found only in small numbers in the duodenum and jejunum of rats and mice which show great numbers in the lower portion of the small intestine. It is also occasionally found in the cecum and large intestine. The life of this parasite is comparatively short in the rat, and it is found to have disappeared or is present only in small numbers 18 days after infection. No evidence has been obtained that the males disappear early in the infection. A sex ratio of one male to two females observed six and seven days after infection has shown no marked change for the ten days following. A male Trichinella has been found in a rat from which all females had disappeared."

Oil of Chenopodium and chloroform as anthelmintics.—Preliminary note, M. C. Hall and W. D. Foster (Jour. Amer. Med. Assoc., 68 (1917), No. 26, pp. 1961-1963).—The authors' experimental findings indicate that oil of Chenopodium should be accompanied by large doses of castor oil, and that when so given it is an uncommonly effective and quite safe anthelmintic for use against ascarids. Chloroform in castor oil, in therapeutic doses, is the most effective anthelmintic that they have found for use against hookworms, and they consider it as safe as thymol or any other effective drug for use against hookworm disease.

Anaphylatoxin and anaphylaxis (Jour. Infect. Diseases, 20 (1917), Nos. 5, pp. 499-656; 6, pp. 657-854, figs. 19).—Ten studies are here reported.

I. Trypanosome anaphylatoxin, F. G. Novy, P. H. DeKruif, and R. L. Novy (pp. 499-535).—In the course of a study on immunity against the trypanosomes of surra and nagana it was found that severe toxic effects with marked hypothermia often followed the injection of autolyzed suspensions of the organisms. Reinjection usually resulted fatally.

This phenomenon was further studied and anaphylatoxin found to be produced by the trypanosomes of surra (Trypanosoma evansi), caderas (T.

equinum), dourine (*T. equiperdum*), nagana (*T. brucei*), and the nonpathogenic trypanosome, *T. lewisi*. The anaphylatoxin was made not only by the living cells but also by those dead and more or less autolyzed, and even by those heated to 60° C. The same mass of trypanosomes could be used repeatedly to toxify different lots of serum. Rat serum was found preferable to guinea pig serum since it yielded a poison 12 or more times as active as that obtained with the latter, the lethal doses being 0.25 cc. and 3 cc., respectively.

"The speed of poison production under favorable conditions is very rapid and quickly reaches a maximum, the poison then persisting for a long time. Thus, infected, defibrinated rat blood or serum, when incubated for one or two minutes, may become fatally toxic. With an incubation of about 15 minutes it is possible to produce a toxic serum such that  $0.25~\rm cc.$  will cause acute anaphylactic death." The anaphylatoxin was found to persist at  $37^{\circ}$  for more than four hours and at about  $0^{\circ}$  for an indefinite time.

"Toxic sera can induce toxicity in normal sera, the mixtures representing a high dilution of the former. This result is not due to the action of a ferment, but to minute amounts of trypanosomes still present in the inciting serum; or, in the case of very prolonged incubation, to the production of autoanaphylatoxin. . . .

"Transfusion experiments indicate the possible presence of anaphylatoxin in heavily infected rats. The formation of this poison in corpore may lead to sudden deaths or to chronic intoxication or cachexia. . . .

"The injection of large amounts of washed trypanosomes into guinea pigs may result in the production of anaphylatoxin in corpore. The effects are not due directly to the organisms but to the disturbance in the colloidal state of plasma constituents caused by the alien material. The 'trypanotoxins' are therefore disturbers of equilibrium; the result is a poison production in vivo as well as in vitro. The mode of action of endotoxins in general will be found to be of the same nature.

"The participation of a ferment in this reaction is contraindicated by the speed of production, the rapid attainment of maximal level, the behavior of inactivated sera, and by the results of centrifugation.

"The syndrome of symptoms and autopsy findings consequent on the injection of the trypanosome anaphylatoxin are those of the intoxication of true anaphylaxis. The two poisonings are to be considered as identical."

II. Agar anaphylatoxin: Guinea pig serum, F. G. Novy and P. H. DeKruif (pp. 536-565).—Anaphylatoxin was produced in guinea pig serum by using agar in place of the trypanosomes. Incubation from 8 to 10 minutes at 37° was found to render the serum fatal in a dose of 3 cc. The lethal dose can be reduced to 1 cc. "The toxicity of such serum, when tested at regular intervals, appears to show more or less oscillation, as in the case of the trypanosome anaphylatoxin. Such variations are not due to a change in the amount of the poison, but to a varying resistance of the test animals. The physical state of the agar is an important factor in the production of the poison,"

Incubation at  $37^{\circ}$  is necessary, and serum contact does not result in poison production, which contraindicates absorption as a factor in the reaction. Individual variation in the ease with which sera can be toxified was noted.

III. Agar anaphylatoxin: Rabbit serum, F. G. Novy and P. H. DeKruif (pp. 566-588).—The production of anaphylatoxin in normal rabbit serum was found not to be as easy as in the case of guinea pig or rat serum. Individual variation in the ease with which the serum yielded the poison was again observed. The presence of lipoidal matter was not found to be inhibitive. After a short fast the sera appeared to be more reactive, and a varied diet was favorable to

the reaction. The results were similar to those noted in the case of the guinea pig serum.

IV. Agar anaphylatoxin: Rat serum, F. G. Novy and P. H. DeKruif (pp. 589-617).—"Rat serum can be toxified with agar in 7.5 minutes so that 0.25 cc. will cause acute fatal shock; after incubation for only 2.5 minutes 1 cc. may be fatal. The reaction concerned in the production of anaphylatoxin is one of great speed. Agar and trypanosomes can work at the same speed since they can toxify 1 cc. in 2.5 minutes.

"The individual sera show some variation in the ease with which they can be toxified. This is not due to the age of the serum or to the presence of lipoids. Normal rat serum, without any addition, on long incubation may become toxic so that 1 cc. will be fatal.

"The physical state of the agar is an important factor in the production of the poison. Its inducing power is not affected by sterilization at 140°."

The poison is not destroyed when kept at 56° for 24 hours, but is partially destroyed in half an hour at 70°, and apparently completely in 5 minutes at 100°.

V. Effect of multiple doses of anaphylatoxin, F. G. Novy and P. H. DeKruif (pp. 618-628).—Rat anaphylatoxin, in amounts representing from 1 to 40 lethal doses, invariably produced death in guinea pigs in essentially the same time. "The larger doses gave an intense quiet shock; the autopsy findings in all cases were typical, but with larger doses the petechiæ in the lungs were most pronounced; the blood was always free from clot. The blood when transferred to a test tube showed delay in coagulation. Slow injection of very large doses gave an almost incoagulable blood. The in vitro mixtures of rat anaphylatoxin and normal blood likewise showed retarded coagulation. The white rat possesses a remarkable immunity against anaphylatoxin; weight for weight it can tolerate more than 100 times as much as the guinea pig. The dosage with serum reached 10 per cent of the body weight. . . .

"The rabbit like the rat is not affected by large doses of anaphylatoxin and this fact parallels the behavior of rabbits on injection of large doses of the toxic antisheep immune rabbit serum. It is this tolerance of the rabbit for the poison that permits the formation of large amounts of anaphylatoxin during life. Antisheep guinea pig serum is not toxic since the formation of anaphylatoxin to the extent of a single lethal dose would mean the death of the animal. This tolerance likewise accounts for the known resistance of the rabbit to specific anaphylaxis."

A transfusion experiment indicated the rapid disappearance of the anaphylatoxin from the blood.

VI. Effect of intravenous injections of agar, F. G. Novy and P. H. DeKruif (pp. 629-656).—Agar injected into guinea pigs may produce a typical anaphylactic shock and death with characteristic autopsy findings. The rabbit appears to be somewhat less susceptible than the guinea pig to the agar injections and the rat still less inactive. "With a transfer time of 1 minute, the transfusion of 4 cc. of normal rat blood resulted in typical fatal anaphylactic shock, due to the anaphylatoxin formed as the result of the precoagulation disturbance.

"The transfusion method has shown that the blood of normal untreated rabbits may be toxic in dose of 2 cc., and that the serum from such animals may be fatal in dose of 1 cc. The apparently healthy rabbit may carry 50 guinea pig lethal doses per kilogram.

"This inherent or acquired toxicity is to be correlated with that developed by immunizing injections, also with the precoagulation toxicity, and with that of normal serum, as well as with that induced in normal serum by alien substances."

It is concluded that the so-called "endotoxin" of various pathogenic organisms is similar to the toxicity of agar, and that the common conception of endotoxin is fundamentally wrong. "The disturbance in the plasma caused by the introduction of alien substances results in the formation of anaphylatoxin, the poisonous effects of which have been erroneously attributed to a liberation of the so-called endotoxin."

VII. Peptone anaphylatoxin, F. G. Novy, P. H. DeKruif, and F. O. Novy (pp. 657–716).—The symptoms and findings in guinea pigs injected with peptone were the same as those produced by anaphylatoxin, agar, or by specific anaphylactic shock. A marked exophthalmos was observed and was especially marked in rabbits. Guinea pigs showed the same individual variation to peptone as has been demonstrated for anaphylatoxin and agar. In white rats the injection of peptone resulted in symptoms and findings identical with those caused by anaphylatoxin and agar. The coagulation time of the blood was retarded for an appreciable period.

It was found necessary to employ very large doses of peptone in rabbits to obtain typical anaphylactic shock and findings. Considerable variation in resistance was observed in rabbits, as in rats and guinea pigs. An immunity or tolerance was shown by the rabbit to repeated injections of peptone similar to that exhibited by the dog or guinea pig.

"Rat serum on treatment with peptone rapidly yields anaphylatoxin. A peptone suspension is more active than a perfectly clear solution. The fully dissolved peptone does not toxify rat serum as easily, nor does it yield as high a degree of toxicity as do the agar and trypanosome suspensoids. Extreme dispersion is, therefore, unfavorable for the reagent." Anaphylatoxin was also produced when guinea pig serum was treated with peptone.

"A comparison of the effective agar-serum ratio with that of peptone-serum shows that, with regard to rat serum, agar is 500 times more active than peptone; with regard to guinea pig serum, it is from 200 to 1,000 times as active. . . . Peptone itself is not toxic, but when brought into contact with a reactive serum or plasma it induces the change which results in anaphylatoxin production."

VIII. The primary toxicity of normal serum, P. H. DeKruif (pp. 717-775).—
"Very rapid transfusion of the blood of normal rabbit to the guinea pig or white rat shows that the toxicity of such blood is subject to great variation. It is often possible to transfuse 10 cc. of heart blood without much effect. Exceptionally, however, the blood from apparently normal rabbits is inherently toxic in dose of 2 or even 1 cc., and the plasma and serum from such blood may be correspondingly toxic. The natural resistance of the rabbit enables it to act as a carrier of the poison which may be generated in the normal animal as a result of changed conditions, notably diet. The toxicity of the blood of an apparently normal rabbit may correspond to 100 guinea pig lethal doses per kilogram. A blood which is initially nontoxic becomes poisonous in 3 cc. dose, just prior to the appearance of coagulation. The speed of poison production corresponds to that of anaphylatoxin by agar, inulin, trypanosomes, etc."

The symptoms and autopsy findings in guinea pigs after injection of toxic blood or serum were essentially those produced by anaphylatoxin and in anaphylactic shock. When rat or guinea pig blood or serum was used instead of that of the rabbit identical results were obtained. Homologous blood was found to be distinctly less toxic than heterologous. Large doses of normal

rabbit serum which killed guinea pigs rapidly caused death with thrombi in the heart and enlarged vessels.

IX. Specific anaphylactic \$hock, F. G. Novy and P. H. DeKruif (pp. 776-832).—It is noted that the rat is an invaluable agent in the study of anaphylaxis. Nonspecific anaphylactic shock was induced in sensitized rats by the injection of distilled water in amounts which had no effect on the normal rat. Salt solution in like doses was tolerated with practically no effect. The specifically sensitized guinea pig was found not to be more susceptible to distilled water than the normal animal.

"The relative behavior of the rat and guinea pig to distilled water is paralleled in the relative ease with which the serum of the former, as compared with that of the latter, is toxified by agar. Normal guinea pigs on rapid injection of very large doses of saline, and especially of distilled water, respond with shock effects. . . . A mixture of distilled water and sensitized rat serum is rapidly toxified at 37° C., the speed increasing with the dilution. The dose containing 1 cc. serum equivalent, incubated for 5 minutes, is fatally toxic." A mixture of distilled water and serum of the rat sensitized to horse serum was likewise rapidly toxified at 37°.

"The speed of poison production in normal serum or in sensitized serum is the same as that which has been demonstrated for agar, trypanosomes, peptone, etc. The in vivo production of anaphylatoxin in specific shock, and its production, in vitro, in mixtures of sensitized sera and antigen or distilled water, is therefore an accomplished fact. The results contraindicate the theories of adsorption and of proteolysis. The specific anaphylactic shock is the result of anaphylatoxin production, in corpore, consequent upon the inducing action of a body which is formed by the union, or otherwise, of antigen and its specific antibody. It is not necessary for this inducing body to exist as a visible precipitate, since substances in solution are capable of giving rise to anaphylatoxin. The specificity of the reaction concerns the production of this inducing substance, and not that of the poison; and further, the antigen is in no wise the source of the anaphylatoxin which is brought into being in shock."

X. Anaphylatoxin and amino nitrogen, P. H. DeKruif and W. M. German (pp. 833-854).—No relationship between serum autolysis and anaphylatoxin production was observed when the method of Van Slyke for the determination of aliphatic amino nitrogen was used.

"Rat and guinea pig sera, toxified rapidly by the addition of 5 per cent agarhydrogel, show a marked decrease in amino nitrogen as compared with controls from the same pool of serum. This decrease takes place at once upon addition of agar to serum. After this preliminary drop in amino nitrogen a very gradual rise to a value not exceeding that of the control may take place. Maximal toxicity appears before this increase begins to be noticeable. The cause of this drop in amino nitrogen in serum treated with agar is not known, but is probably to be referred to adsorption of amino acid by the agar. Attempts to recover this supposedly adsorbed amino acid have failed.

"A similar drop in amino nitrogen along with a marked increase in toxicity is to be observed in the case of rat serum incubated with inulin. Guinea pig serum treated in a like manner shows a slight increase in amino acids, which, however, does not keep pace with the increase in toxicity. Rat serum behaves peculiarly when diluted with distilled water. Sensitive rat serum shows an increase, normal rat serum a decrease in amino nitrogen when incubated with six volumes of distilled water. Despite this difference, both become toxic."

The most potent anaphylatoxin was produced by mixing inulin in the proportion of 1 to 10 with normal rat serum.

A study of five members (or so-called species) of the septicemia hemorrhagica (Pasteurella) group of organisms with special reference to their action on the various carbohydrates, A. M. Besemer (Jour. Bact., 2 (1917), No. 2, pp. 177-184).—"The members of the septicemia hemorrhagica group studied were practically uniform in their biochemical actions. The passing of an organism through a rabbit did not change its biochemical characters, except to a very slight degree."

The virulence of apparently sound muscle and lymph glands in general bovine and porcine tuberculosis, P. Chaussé (Ann. Inst. Pasteur, 31 (1917), No. 1, pp. 1-18).—The literature on the subject is reviewed and data submitted in tabular form.

In the original study reported material from 18 tubercular hogs and 40 tubercular cattle was used. Extracts were made of the muscular and lymphatic tissue and injected into guinea pigs. Of the animals injected with the material obtained from the muscle tissue none exhibited tubercular symptoms or lesions on autopsy. These results indicate the freedom from virulent material of the muscles of animals which have died from the disease. Of 53 samples of lymphatic material 13 were found to be virulent. The relative frequency of the virulence of this material is considered to be strong proof of the rôle of filtration of the lymphatic system as a defensive agency.

The results of the investigation are discussed and their hygienic importance emphasized.

Eupatorium ageratoides, the cause of trembles, R. S. Curtis and F. A. Wolf (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 11, pp. 397-404, pls. 3).—This is a progress report of investigations conducted at the North Carolina Experiment Station, in the mountainous sections of which State considerable losses of domestic animals result from a malady known as trembles. The disease is thought to be transmissible to man through milk products or flesh of animals affected with the disease, and is known by physicians as milk sickness.

The report is summarized as follows: "E. ageratoides, commonly known as white snakeroot and locally known in North Carolina as richweed, had previously been claimed by Moseley [E. S. R., 21, p. 383] to cause trembles in animals. This claim has been substantiated by experiments with sheep in which green plants of E. ageratoides were fed during the months of June, July, August, September, and October, 1916. Fifteen cases of trembles in sheep have been developed from feeding E. ageratoides. Fourteen of these resulted fatally and one of them recovered. Death of one of these sheep was probably due in part to an infestation of stomach worms. Death resulted in from 5 to 27 days following the beginning of feeding of E. ageratoides. Considerable variation existed in the several ewes, also, with reference to the quantity of weed ingested before trembles appeared.

"Indirect evidence against the infectious nature of the disease was secured by failure to communicate trembles from sheep characteristically affected to healthy sheep when they were confined and fed together in a small lot.

"Salt and soda in the amounts given along with a ration of grain and E. ageratoides were without apparent antidotal effect. No harmful effect followed the feeding for 69 days of aluminum phosphate mixed with grain and supplemented with alfalfa hay."

The control and prevention of infectious diseases of cattle, E. C. SCHROEDER (Ann. Rpt. Internat. Assoc. Dairy and Milk Insp., 5 (1916), pp. 167-180).

The bacteriotherapeutic treatment of ulcerous lymphangitis in the horse, C. Truche (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 12, pp. 497-499).—

The successful treatment of the disease with a vaccine made from the Preisz-Nocard bacillus is noted.

The vaccine was prepared by heating a suspension of the organism in physiological salt solution for 24 hours at 37° C., separating the organisms by centrifugalization, treating with alcohol-ether mixture, and finally drying over sulphuric acid. It produced no general reaction, the thermic reaction being only from 0.5 to 1° and the appetite and general condition remaining normal. The number of injections found necessary varied with the degree and duration of the disease, two or three generally being sufficient. The value of local treatment with tincture of iodin and other antiseptics is noted.

Salvarsan in the treatment of canine distemper, C. Krocheb (Abs. in Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 4, pp. 565, 566).—It appears that salvarsan does not exert either a curative or an otherwise favorable action on the course of canine distemper.

On the occurrence of a pseudoparasitic mite (Cheletiella parasitivorax) on the domestic cat, S. Hibst (Ann. and Mag. Nat. Hist., 8. ser., 20 (1917), No. 115, pp. 132, 133, fig. 1).—This records the finding, on post-mortem examination of a cat affected with mange, of numerous specimens of C. parasitivorax on various parts of the body and a few isolated eggs, each fixed to a hair. Presumably this mite fed on the acarid Notwdrus cati.

Chicken pox in poultry.—Preventive suggestions based on practical experiments, H. E. Upton (*Brit. Columbia Dept. Agr., Circ. Bul. 20 (1917), pp. 5, figs. 5*).—The author has vaccinated approximately 3.000 birds ranging from 5 weeks to 3 years in age without observing any bad effects aside from 3 deaths, due mainly to emaciation before vaccination. Control birds were left in each flock, and 40 per cent died. Egg production was not affected by vaccination in any way other than the handling of the birds would cause.

"Some flocks were vaccinated with vaccine made from scabs only. Others were vaccinated from vaccine made from scabs and cheesy exudate. Some were vaccinated with vaccine made up of scabs and exudate mixed together before attenuated. Others were vaccinated with vaccine made by attenuating scabs and exudate separately and mixing the two vaccines together before injection. The best results were obtained amongst the 7 flocks by the use of the vaccine made up of the scabs and exudate ground together before being attenuated.

"Data were not obtainable from any source relating to the vaccination of young chicks. Our experiments show that good results are obtainable by vaccinating 5- to 8-week-old chicks (majority showing signs of disease after severe chilling) twice with 0.5 cc. of vaccine at intervals of 3 to 4 days. Two cc. was injected in 3 or 4 very bad cases expected to die in a few hours. Cases recovered and can not be noticed other than by band number in flocks after expiration of 7 months.

"Strong tincture of iodin is recommended as the best disinfectant for use with this disease. The scabs and exudate should be removed with a sterile pair of forceps and tincture of iodin applied to the exposed surface."

#### RURAL ENGINEERING.

A textbook of practical hydraulics, J. Park (Philadelphia: J. B. Lippincott Co., 1916, pp. XVI+284, pls. 47, figs. 115).—This is a handbook for the practical use of irrigation, hydraulic, and power development engineers. It comprises chapters on some first principles: definition of terms; flow of water through orifices; friction in pipes and channels; the discharge of pipes; flow of water

in open channels, over weirs and notches, and in rivers; construction of pipes, flumes, ditches, masonry and concrete dams, and earthen dams; and water power and water prime motors.

Report of the State water commission of California, 1917 (*Rpt. State Water Com. Cal., 1915–16, pp. 183, pls. 10, flgs. 5*).—This report contains data on water rights and water supply in California, duty of water, ground water and its relation to surface water, water spreading, check dams, interstate water rights, rice culture, the irrigation districts of California, and the principal private irrigation enterprises. A list, by counties, of all applications for the appropriation of water, together with a statement of their status, is included.

Report of the water conservation and irrigation commission [of New South Wales] for the year ended June 30, 1916 (N. S. Wales Rpt. Water Conserv. and Irrig. Com., 1916, pp. 128, pls. 10).—This report for 1916 contains data on irrigation areas in New South Wales established and controlled by the State, irrigation schemes under consideration for State control, water conservation works constructed by the State but administered by local trusts, national works maintained by the commission, artesian and shallow boring, and water conservation and irrigation works constructed by private persons. Eleven appendixes of financial and statistical data are included.

Administration report, irrigation department, Punjab, 1915-16 (*Punjab Irrig. Branch Admin. Rpt. 1915-16*, pp. 178, pls. 13).—This is an administrative report, including statistical data on expenditures and revenues for irrigation in the Punjab.

Surface water supply of North Atlantic slope drainage basins, 1915 (U. S. Geol. Survey, Water-Supply Paper 401 (1917), pp. 155+XXXVI, pls. 2).—This report contains the results of measurements of flow made on the drainage basins of streams in the North Atlantic slope during 1915, together with the usual list of gauging stations and publications.

Surface water supply of Ohio River Basin, 1915 (U. S. Geol. Survey, Water-Supply Paper 403 (1917), pp. 175+XXXIV, pls. 2),—This report presents the results of measurements of flow made on streams in the Ohio River Basin during 1915, together with the usual list of stream-gauging stations and publications.

Centrifugal pumps and suction dredgers, E. W. Sargeant (Philadelphia: J. B. Lippincott Co., 1916, pp. VIII+188, pls. 16, figs. 131).—This book is essentially a manual of centrifugal pumping machinery for the use of engineers and designers and those responsible for the installation and supervision of centrifugal pumping plants. It contains chapters on the design and construction of centrifugal pumps of different types; pumps in series and parallel; high capacity, low-head pumps; charging apparatus; testing of centrifugal pumps; centrifugal pumping machinery for drainage, irrigation, and sewage; and pumps for dredging and conveying solids.

Some costs of maintenance of motor-driven deep-well pumps, M. L. ENGER (Jour. Amer. Water Works Assoc., 4 (1917), No. 2, pp. 190, 191).—Records made at the University of Illinois are reported.

Unlined earth reservoirs for pumping plants, (Jour. Electricity, 38 (1917), No. 10, pp. 395-397, figs. 2).—Cost data per acre-foot for different capacities of unlined reservoirs for irrigation are graphically given, together with tabular and other data on the details in the construction of typical unlined earth reservoirs.

Pumping for irrigation on the farm, P. E. Fuller (U. S. Dept. Agr. Year-book 1916, pp. 507-520, pl. 1, fig. 1).—This article deals with types of pumps and their special adaptations, and with the general features of proper installation of an irrigation pumping plant, including well construction.

With regard to cost, it is stated that "a first-class pumping plant, including well, may be installed, under average conditions of head and capacity, at a cost of from \$5,000 to \$7,000, with ample capacity to irrigate 160 acres of average forage crops. A smaller plant with a capacity of several hundred gallons a minute may be installed complete, including the well, for \$2,000 or less if water-supply conditions are favorable. The cost of a reservoir may be \$500 or even \$1,000 if it be concrete lined. The operation of a pumping plant should extend over as great a period of time during an irrigation season as possible, so as to reduce the unit overhead cost."

Divisors (for the measurement of irrigation water), V. M. Cone (Colorado Sta. Bul. 228 (1917), pp. 3-52, figs. 8).—This bulletin, based on work done under a cooperative agreement between the Colorado Station and the Office of Public Roads and Rural Engineering, U. S. Department of Agriculture, reports the results of 341 tests of divisors for the measurement of irrigation water and 196 tests on dividing the flow over rectangular and Cipolletti weirs. Eight different divisors were tested, each under four different sets of conditions.

In the weir tests "crest lengths of 2 and 4 ft. were used for both types. A thin metal plate was placed on the downstream side of the weir so that its edge touched the crest of the weir and extended vertically above the weir crest into the weir notch. This plate was set for different experiments at intervals of 2 in. across the entire width of the weir, and separate channels caught the flow over the weir on the two sides of the plate. These channels were placed far enough below the crest of the weir to allow a free passage of air under the overpouring sheet of water.

"Under these conditions both types of weirs give reasonably accurate divisions, the greatest error being with the rectangular weir set to divide the flow between two parties on a basis of one-fourth and three-fourths, when the actual deliveries will be 24 and 76 per cent for a head of 0.2 ft., and 22.5 and 77.5 per cent for a head of 0.8 ft. The errors with Cipolletti weirs used as divisors were in the opposite direction and about one-half as great. When either weir would be used to divide the water equally between three parties the error would be quite negligible.

"If the divisor plate is placed out some distance from the weir, or the edge is placed in a horizontal position below the weir crest, the discharge for the end division would be considerably short, and the flow for the middle division would be accordingly greater than the desired amount."

The composition of irrigation waters in upper Italy, A. Menozzi and A. De Vecchi (Rend. R. Ist. Lombardo Sci e Let., 2. ser., 49 (1916), No. 7-8, pp. 291-297).—Analyses of representative samples of irrigation waters from irrigation canals of Lombardy are reported and discussed.

The economical irrigation of alfalfa in Sacramento Valley, S. H. BECKETT and R. D. ROBERTSON (California Sta. Bul. 280 (1917), pp. 273-294, figs. 2).— This bulletin reports the results of work done under cooperative agreement between the Office of Public Roads and Rural Engineering, U. S. Department of Agriculture, and the State Engineering Department of California, and between the Office of Public Roads and Rural Engineering and the California Experiment Station. The practices found most desirable are summarized in the table following.

Results of studies of alfalfa irrigation practices.

Soil type.	Number of irrigations.	Depth of each irrigation.	Total depth of irrigation.	Desirable dimensions of checks.		Desira-	Desir- able irriga-
				Width.	Length.	ble grade of checks. per 100 feet.	tion heads per second per check.
Medium loam Gravelly or sandy soil Heavy soil	3 to 5	Inches. 6 to 9 3 to 4 2 to 4	Inches. 30 to 36 48 to 60 30 to 36	Feet. 50 100 30 to 50	Feet. 300 to 600 100 300 to 600	Inches. 3 to 6	Cu.ft. 2 to 10 5 to 6

The general conclusion drawn is that "from 2.5 to 3 acre-feet of irrigation water per acre per year is sufficient for the growth of maximum economic yields of alfalfa on the medium loam soils of Sacramento Valley."

Irrigation and drainage, E. RISLER and G. WERY (Irrigations et Drainages. Paris: J. B. Baillière & Sons, 1916, 3. ed., rev. and enl., pp. 566, figs. 186).—This is the third revised and enlarged edition (E. S. R., 15, p. 934) of one of the volumes of the Encyclopédie Agricole.

Part 1, on water plants and the soil, contains chapters on the physical and chemical relations between water, soil, and plants; the régime of water in geological formations; and fertilizing substances. Part 2, on irrigation, contains chapters on effects of irrigation; quality, methods of obtaining, and distribution of irrigation water; cost, technique, assessments, practice, and economics of irrigation; irrigation ditches and canals; duty of water; drainage of irrigated lands; irrigation in mountain regions; silting; maintenance of prairie irrigation systems and prairie irrigation practice. Part 3, on drainage, contains chapters on the origin, indications, and bad results of excess of water in soil; reclamation and drainage and methods therefor; definition and history of drainage; theory, execution, and results of drainage; obstructions of drains and methods of prevention; drainage economics; and types of drains and their proper use.

Drainage of irrigated farms, R. A. Hart (U. S. Dept. Agr., Farmers' Bul. 805 (1917), pp. 31, figs. 19).—This describes methods of draining irrigated farms. See also a technical report by the author (E. S. R., 33, p. 88).

Standard specifications for drain tile (Amer. Soc. Testing Materials, A. S. T. M. Standards, 1916, pp. 452-468, pl. 1, figs. 4).—Specifications for farm, standard, and extra quality drain tile are given as issued for 1916.

The quality of water and confirmatory tests for Bacillus coli, A. Wolman (Jour. Amer. Water Works Assoc., 4 (1917), No. 2, pp. 200-205, fig. 1).—Experimental data are reported from which it is concluded that "a water showing the highest degree of actual pollution, as determined by the highest percentage of samples giving a positive isolation test for colon, in general gives the highest percentage of presumptive tests confirmed. A water showing the lowest degree of actual pollution in general gives the lowest percentage of presumptive tests confirmed. . . .

"A rough quantitative test for pollution, in a general study of a water, might with safety consist only of a determination of the presumptive tests confirmed, rather than of a detailed estimate of the percentage of samples showing isolation tests in varying dilutions. In such a procedure one might establish as bases for comparison a maximum and minimum percentage of tubes confirmed, using for this purpose waters grossly polluted in the first case, and unquestionably

pure in the second. With these maximum and minimum values as standards, the relative position of the water under consideration could be determined with ease by the use of the 'percentage of tubes' scoring method."

Ultra-violet rays, their advantages and disadvantages in the purification of drinking water, R. R. Spencer (Jour. Amer. Water Works Assoc., 4 (1917), No. 2, pp. 172-182, figs. 2).—The author expresses the opinion that the use of ultra-violet rays in the purification of drinking water is capable of further development, with a corresponding increase in efficiency.

"The method is especially recommended for treating water in circulating systems, in which the water may be exposed many times to the ultra-violet rays.... The chief advantages of this method of treatment over chemical methods lie in the fact that objectionable overdosage is impossible. Again, from the standpoint of potability, the water is absolutely unchanged, and, hence, in this respect, is superior even to boiled water....

"The present forms of apparatus need considerable attention when in operation. Care should be taken to prevent an accumulation of grease or dirt of any kind on the quartz tube. Experience has shown that a very small amount of grease will obstruct the light sufficiently to allow many organisms to pass. Furthermore, the light chamber should be emptied if the machine remains idle for any length of time. This will prevent the growth of algae and other organisms which will obstruct the light when the machine is again operated. . . .

"In the tests [described], since the gravity type gave a higher efficiency than the pressure type, and inasmuch as any lamp operating at a higher voltage is known to emit a larger amount of ultra-violet radiation, the use of lamps at a higher voltage, combined with the gravity system, suggests itself as a reasonable line of development. In regard to cost, the method is not expensive when treating relatively small quantities of water."

Sterilization by liquid chlorin and hypochlorite of lime, M. S. Dutton (Jour. Amer. Water Works Assoc., 4 (1917), No. 2, pp. 228-230).—A comparison of calcium hypochlorite and liquid chlorin for water sterilization showed that, "the cost of hypochlorite being considered as 7 cts. per pound and the cost of liquid chlorin as 20 cts. per pound, the average cost of sterilization by means of hypochlorite was \$1.07 per million gallons of water treated and 28 cts. per million gallons when using liquid chlorin. The saving, then, in chemicals alone amounted to 79 cts. per million gallons of water treated.

"In summarizing the results of sterilization, the average reduction in bacteria count of daily plates made on nutrient agar incubated at 37° C. for 24 hours was as follows: In January, when hypochlorite was used, the average raw water count was 6.300 and the filtered water count was 15. In June, when liquid chlorin was used, the average raw water count was 7,980 and the filtered water count was 11. In Bacillus coli tests, the raw water shows 100 per cent + for both months, while the filtered water shows 1.6 per cent + in January and 0 per cent + in June. These results were obtained by means of 1 cc. samples in all cases. While hypochlorite was used 0.46 parts per million of chlorin was applied and while using liquid chlorin 0.22 parts per million of chlorin was applied."

The disposal of wastes from the dairy industry, A. E. Kimberly (Ohio Pub. Health Jour., 7 (1916), No. 7, pp. 250-285, pl. 1; abs. in Chem. Abs. 10 (1916), No. 21, p. 2779).—This paper reviews existing information on the dairy wastes disposal problem, covering American and foreign experience, and suggests practical solutions of given problems, including plant design and estimates of cost. It is based especially on experience by the Ohio State Board of Health. The following conclusions are drawn:

"Not only do the actual wash waters cause nuisances, but in a practical way also whey, buttermilk, and skimmed milk remaining at the end of the day's operation, all three of which require extended dilution to admit of their satisfactory disposal in running streams. . . . No practical process appears available for whey treatment unless the small plant ships the waste to a central station for evaporation. Whey-butter making would, of course, remove but little of the organic matters of the whey. Whey contains so much albuminous matter as to render ineffective the bacterial processes availed of in the treatment of the other wastes of the dairy industry and its removal by cartage appears the most practical method of disposal at present available. . . . Dependable whey disposal in a practical way means definite provision for its systematic removal through such part of the year as dilution disposal in the local stream can not be employed.

"Tank treatment by septic tanks requires land or artificial filters in the absence of 30-fold dilution. With proper construction . . . tanks of 48 or 72 hours' retention, according to the character of the processes carried out at the plant, and filters of sand on a basis of 25,000 gal. per acre per day, can be depended upon to prevent nuisances. The rectangular tank has at best certain disadvantages, particularly as regards the intermittent discharge of sludge with the effluent. Data are too few to indicate the applicability of two-story tanks, but it would seem that such tanks can be advantageously used for wastes of the dairy industry, subject to proper construction details, especially as to detention period. Combined septic and two-story tanks may solve this problem to good advantage. . . .

"Tanks remove suspended matter, increase acidity by encouraging the lactic fermentation, and to a certain extent modify the chemical character of these wastes. Filters, subsurface tile systems, or running streams supply the oxygen essential to render the organic matters of these wastes no longer amenable to putrefactive decomposition. Each has its own function to perform. These processes cover the field at present available for waste treatment. All methods applicable to the treatment of domestic sewage have been applied in the past with varying degrees of success to dairy wastes, and it is possible that the activated sludge process may find in these wastes a fruitful field. Unless activated sludge methods will result in by-product recovery, bringing financial gain to the plant, it is the author's viewpoint that the process would be of limited utility because the operation of such plant would involve a daily expense and because dairy waste disposal to be successful under practical conditions must be cheap and simple in operation and require but little daily attention."

Forty-two references to literature bearing on the subject are appended.

Sewage disposal on the farm, G. M. WARREN (U. S. Dept. Agr. Yearbook 1916, pp. 347-373, figs. 10).—This article deals with sewage as a menace to health and with sewage purification by natural agencies, and describes and diagrammatically illustrates pit, dry earth, and wet closet privies, chemical closets, cesspools, and septic tanks.

An especially important point brought out regarding septic-tank systems is that "the septic tank is not a complete method of sewage treatment. With the general run of small septic tanks it is close to the facts to say that of all the solid matter in the crude sewage one-third is reduced to liquids and gas, one-third remains in the tank, and one-third escapes with the effluent. Every septic-tank installation is a problem by itself. As a suit is fashioned to the size and needs of an individual, so should the design of a septic tank and the after disposition of the effluent be decided upon, with full consideration for the size of the family, the amount of water used, the location of property lines, buildings, wells, and drainage outlets, the slope of the land, and the character of the soil and subsoil."

Modern road construction, A. T. Byrne (Chicago: Amer. Tech. Soc., 1917, pp. [VIII]+187, pl. 1, figs. 113).—This is a treatise on the engineering problems of road building, with a compilation of highway specifications. It is the purpose to cover the field of road building for both rural and urban conditions. The following chapters are included: Country roads and boulevards—resistance to movement of vehicles, location of roads, preliminary road construction methods, culverts, earthwork, and maintenance and improvement of roads; city streets and highways—foundations, stone-block pavements, brick pavements, wood-block pavements, asphalt pavements, miscellaneous pavements, miscellaneous street work, curbstones and gutters, street cleaning, and selecting the pavement.

Good roads yearbook, 1917 (Good Roads Year Book, Amer. Highway Assoc., 1917, pp. VII+556, figs. 36).—This is the sixth annual edition of this book (E. S. R., 35, p. 583). It gives information regarding road improvements under Federal, State, Territorial, and local control and on the construction and maintenance of rural roads and miscellaneous information and tables.

Report of the State highway commission of Minnesota, 1915–16 (*Rpt. Highway Com. Minn.*, 1915–16, *pp. 40*, *pls. 3*, *figs. 16*).—This is a report on the work and expenditures on road and bridge design, construction, and maintenance in Minnesota during the years 1915–16, including data on reinforced concrete bridge and culvert tests.

Wisconsin highway commission, second biennial report (Wis. Highway Com. Bien. Rpt., 2 (1913-14), pp. IX+260, pls. 5, figs. 85).—This is a statement of work and expenditures on highway construction, maintenance, and repair in Wisconsin for the two calendar years ended December 31, 1914, together with the cost of construction for the year 1912.

The highway law [of New York] (Albany, N. Y.: State, 1916, pp. 344).—The text of the law is given.

Automobile registrations, licenses, and revenues in the United States, 1916 (U. S. Dept. Agr., Office Sec. Circ. 73 (1917), pp. 15, fig. 1).—This circular was prepared in the Office of Public Roads and Rural Engineering.

"In 1916 a total of 3,512,996 motor cars—including commercial vehicles—and 250,820 motorcycles, were registered in the several States on account of which the States collected in registration and license fees, including those of chauffeurs and operators, a total gross revenue of \$25,865,369.75. As compared with 1915, this was an increase of 1,067,332 cars, or 43 per cent in number, and \$7,619,659, or 42 per cent in revenue. This corresponds very closely to the annual percentage increase of the three preceding years, which was about 40 per cent for motor cars and 50 per cent for revenues."

Data are also reported showing motor vehicle registrations and license fees in force January 1, 1917, and administrative provisions in force January 1, 1917, affecting motor vehicle registrations, licenses, and revenues.

A treatise on concrete, plain and reinforced, F. W. TAYLOB and S. E. THOMPSON (New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1916, 3. ed., rev. and cnl., pp. XX+885, pl. 1, figs. 268).—This is the third revised and enlarged edition of this book (E. S. R., 28, p. 186). The most important changes are in the portions treating of reinforced concrete. Prominent among the additions in the first part of the book are specifications for reinforced concrete and new cement specifications.

Extracting alcohol from garbage would conserve vast quantities of grain and potatoes (*Engin. News-Rec.*, 78 (1917), No. 11, pp. 534, 535, fig. 1).—Experiments at the Columbus, Ohio, garbage reduction works showed "that 1 ton of Columbus green garbage will yield 4.8 gal. of 95 per cent alcohol of satisfactory quality. Estimates indicate that a \$36,000 plant would produce from

the 20,000 tons of garbage treated annually at the reduction works a total of 96,000 gal. of alcohol, giving a profit of 42 cts. per gallon at war-time prices or 30.5 cts. under normal conditions. A year's garbage, the tests indicate, would yield as much alcohol as could be produced from 33,600 bu. of shelled corn, 39,529 bu. of wheat, or 110,344 bu. of potatoes. . . .

"The process consists of extracting grease from garbage by cooking with sulphuric acid and steam, thereby converting the starch and allied products to dextrose, separating the grease from the tank liquor, neutralizing the acid sufficiently to allow fermentation, fermenting the liquor with yeast, thereby converting the dextrose to alcohol, and then recovering the alcohol by distillation."

Agricultural practice, T. H. LOUGHEB (Estac. Expt. Agron. Cuba Bol. 31 (1916), pp. 35, pls. 30).—This bulletin deals mainly with the types of machinery best adapted to Cuban agriculture and discusses soils and crops in general.

The necessity of mechanical cultivation of soil, G. Héron (*Prog. Agr. et Vit.* (*Ed. l'Est-Centre*), 37 (1916), No. 29, pp. 61-69).—This is a brief comparison of animal with motor power, made on the basis of net expense of cultivating a hectare of soil for one year.

Public tests of motor cultivation, J. H. Sourisseau (Prog. Agr. et Vit. (Ed. l'Est-Centre), 37 (1916), Nos. 30, pp. 82-93; 32, pp. 133-138; 33, pp. 160-166; 34, pp. 178-180; 35, pp. 205-212, figs. 12).—Tests of a number of motor plowing and cultivating outfits are reported and discussed. The purpose was to determine some of the factors in the selection of motor-drawn tillage machines and the cost of different motor tillage operations under French conditions.

Homemade silos, F. M. HILLMAN (Mont. Col. Agr. Ext. Serv. [Pub.] 21 (1917), pp. 31, figs. 23).—This circular describes the construction of different types of silos under Montana conditions, special attention being given to the less expensive types such as the pit silo.

How to build the wooden-hoop silo, R. U. BLASINGAME (Ala. Polytech. Inst. Ext. Serv. Circ. 9 (1917), pp. 6-12, pls. 4, figs. 2).—This circular describes the construction and gives bills of materials and costs for several sizes of wooden-hoop silo.

The Tennessee wood-hoop silo.—How to build it, C. A. HUTTON (Col. Agr. Univ. Tenn., Ext. Div. Pub. 26 (1917), pp. 19, ftgs. 15).—This circular describes the construction of wooden-hoop silos under Tennessee conditions.

A dairy farm plant, I. D. CHARLTON (Washington Sta., West. Wash. Sta. Mo. Bul., 5 (1917), No. 3, pp. 35-39, figs. 4).—This plant is described and diagrammatically illustrated.

Cooling tanks and milk houses as factors in cream improvement, J. H. Frandsen (Nebraska Sta. Circ. 3 (1917), pp. 19, figs. 13).—This describes and illustrates cream cooling tanks and milk houses, and gives the results of winter and summer tests of a square tank built of 2-in. cypress, a square tank insulated with 1 in. of ground cork or mineral wool, and a round tank built of 2-in. Washington fir.

In the summer tests it was found that the difference in the results obtained with these three tanks was so slight that one would scarcely be jusified in going to the expense of providing insulation other than that furnished by the wood itself. The water within the tank responded slowly to a change in atmospheric temperature.

"In the winter experiments the tanks were exposed out-of-doors. The only protection given consisted of a double layer of 10-oz, canvas thrown over the top of the tank. In these experiments the water was adjusted at 6 p. m. daily to a temperature at or as near as possible 50° [F.] (the temperature of the well water). Twice daily record was made of the temperature of the cream in each

tank... Although the temperature dropped below zero on several occasions the temperature of the cream remained well above the freezing point. On the coldest nights a very small amount of ice was in evidence on the surface of the cream, but this condition did not exist below the surface, showing that the volume of water in one of these tanks is sufficient protection, even in rather cold weather."

Brief sections on ice for cream cooling and on cream grading and improvement are also included.

Why hot water pipes in household plumbing burst more frequently than cold water pipes, F. C. Brown and W. Noll (*Proc. Iowa Acad. Sci.*, 23 (1916), pp. 237-240).—Experiments are reported on the difference in the time required to burst hot and cold water plumbing pipes and the reasons therefor.

"In summing up the results of the experiments it was concluded that the occluded air affects the difference in bursting. It does this, first, by acting as a nucleus for crystallization, so that ordinary water freezes less solidly than boiled water; second, by causing the ice to freeze less solidly especially at the center, until a very low temperature is reached the pressure along the center is relieved by the water and slush flowing away. Third, the air acts as a compressible medium, which relieves the pressure by an unknown amount."

Community sanitation (Winthrop Normal and Indus. Col. S. C., Home Demonstr. Course for Women, 2. ser., No. 4 [1917], pp. 12).—This is an outline of proposed activities in rural sanitation, including water supply, sewage disposal, fly and mosquito control, etc.

### RURAL ECONOMICS.

Meeting the farmer halfway, C. Veodman (U. S. Dept. Agr. Yearbook 1916, pp. 63-75).—The development of the Federal Department of Agriculture, in response to a demand on the part of the farmers of the country, is briefly traced, and some of the results obtained enumerated. Special notice is made of the increased attention given to the dissemination of information under the Extension Act and otherwise, and to the organization of the Office of Markets and Rural Organization to assist the farmer in solving problems of distribution. Other recent legislation under the Federal Farm Loan Act, Grain-Standards Act, Warehouse Act, Federal-Aid Road Act, and Cotton-Futures Act is also reviewed.

The Nonpartisan League, C. E. Russell (Pubs. Amer. Social. Soc., 11 (1916), pp. 31–36).—An account is given of this league, organized recently by the farmers of North Dakota. Its principles are said to introduce the State into business in the owning and operating of elevators, flour mills, and packing plants at terminal points. It also advocates State insurance against hail, State loans to farmers, and aid in general to make farming more practical and profitable.

Rural surveys, C. W. THOMPSON (Pubs. Amer. Sociol. Soc., 11 (1916), pp. 129-133).—This paper enumerates the purposes for which surveys are made, kinds of surveys made, sources of information, and methods used.

The results of some rural social surveys in Iowa, G. H. Von Tungeln (*Pubs. Amer. Sociol. Soc.*, 11 (1916), pp. 134-162).—The author defines the purposes of rural surveys and the argument for making them. The results of detailed surveys of two Iowa townships are given under (1) population and conjugal conditions, (2) economic conditions, (3) organizations, (4) church and Sunday school membership, and (5) social conditions and the social mind.

The mind of the farmer, E. R. GROVES (Pubs. Amer. Sociol. Soc., 11 (1916), pp. 47-53).—Influences that tend to shape the mind of the farmer are the occupation of farming itself, his isolation, and suggestions from various

sources. The author concludes, however, that owing to the differences between rural communities and close relationship of rural and urban people, no distinctive American farmer's mind is conceivable.

The development of rural leadership, G. W. FISKE (*Pubs. Sociol. Soc.*, 11 (1916), pp. 54-70).—The author considers influences in the rural community itself, such as rural individualism, lack of socialization, and natural difficulties of development, that hinder the development of rural leadership. He concludes that the rural community will organize and develop its leadership from within its own ranks.

The consolidated school as a community center, J. H. Cook (*Pubs. Amer. Sociol. Soc.*, 11 (1916), pp. 97-105).—The author contrasts the advantages of the consolidated school with the one-room school. His conclusion is that "every improvement in rural life and education depends either partially or entirely upon the centralization of schools for its permanent success."

Social control: Rural religion, C. O. GILL (*Pubs. Amer. Sociol. Soc.*, 11 (1916), pp. 106-112).—Resident ministers and interdenominational cooperation is deemed necessary to organize the rural church more effectively. The author considers this action basic for cooperation in rural business as well as for the conservation of rural life itself.

Countryside and Nation, G. E. VINCENT (Pubs. Amer. Sociol. Soc., 11 (1916), pp. 1-11).—This article is a review in its broader aspects of American agriculture to-day. The problem of tenancy and the possibility of land ownership by large corporations are contrasted with the more auspicious tendency to individual ownership.

Country versus city, W. H. Wilson (*Pubs. Amer. Sociol. Soc.*, 11 (1916), pp. 12-20).—The relations between country and city are discussed. The author concludes that the country and city are dynamically one.

Folk depletion as a cause of rural decline, E. A. Ross (*Pubs. Amer. Sociol. Soc.*, 11 (1916), pp. 21-30).—From a personal survey of several rural counties in New England, as well as other districts in various parts of the country, the author concludes that the evident rural decline is due to migration of the natural leaders and not to rural degeneracy. Several remedies for folk depletion are suggested.

Farm tenantry in the United States, W. J. SPILLMAN and E. A. GOLDEN-WEISER (U. S. Dept. Agr. Yearbook 1916, pp. 321-346, figs. 9).—The authors discuss the conditions with reference to tenantry in different parts of the United States.

They conclude that where land is increasing rapidly in value, unless other factors have a preponderating influence, there is a tendency for the percentage of tenantry to increase, while where land is increasing slowly in value the percentage of tenantry does not tend to increase. Among the factors that reduce the normal percentage of tenantry are the availability of public lands, smallness of farms, and low productivity of land. Factors that tend to increase the percentage of tenantry include large size of farms, high productiveness of land, and the capitalization of the advantages of land ownership. The authors also point out that tenantry is encouraged by the higher rate of income on working capital than on fixed capital.

The principal defect of the American system of tenant farming is considered to be the lack of suitable provision for maintaining the fertility of the soil.

The land problem and rural welfare, P. L. Voor (*Pubs. Amer. Sociol. Soc.*, 11 (1916), pp. 82-94).—The author finds the essence of the problem in the centralization of land ownership and the resulting increase in tenantry. Development of a more successful agriculture and better rural life occurs only through effective organization depending on intelligence, homogeneity of popula-

tion, stability, intimate acquaintance, and community of social interests. Increase in tenantry destroys each one of these as a basis of successful organization.

The solution of the problem is thought to be in State action as well as through individual education.

Cooperation and community spirit, A. D. WILSON (Pubs. Amer. Sociol. Soc., 11 (1916), pp. 113-125).—Farmers' clubs with their social, educational, and business activities, and live-stock shipping associations, are cited by the author as examples of successful rural cooperation, while the cooperative store, however, is regarded as one form of cooperation likely to fail. The attitude of Minnesota business men and farmers and that of the U. S. Department of Agriculture and the University of Minnesota toward rural cooperation is explained.

Business essentials for cooperative fruit and vegetable canneries, W. H. Kerr (U. S. Dept. Agr. Yearbook 1916, pp. 237-249).—The author believes that although cooperative canneries sold only \$3,500,000 worth of the approximately \$158,000,000 worth of canned fruits and vegetables marketed in 1914, they have a legitimate place in the marketing of perishable products. A close examination of the many failures as well as the successes indicates that the business of canning is not a by-product business, that a suitable location is vital, that ample capital must back the enterprise, that an experienced manager salesman must be secured, that contracts with growers are necessary, that a liberal and inclusive budget be followed, that cost accounting methods be adopted, and that goods be packed to meet market demands.

A federated cooperative cheese manufacturing and marketing association, H. Macpherson and W. H. Kerr (U. S. Dept. Agr. Yearbook 1916, pp. 145-157).—A survey is given of the cheese industry of Tillamook County, Oreg., where much success is reported to have followed the formation of a cooperative county creamery association in 1909. The plan of operation, benefits of centralized market control, and quality standardization, and the business practice followed are described.

Farmers' mutual fire insurance, V. N. Valgren (U. S. Dept. Agr. Yearbook 1916, pp. 421-433, figs. 4).—The author traces the origin and growth of this form of insurance and discusses its practical workings and possibilities. See also a previous note (E. S. R., 37, p. 391).

State hail insurance in North Dakota (Internat. Inst. Agr. [Rome], Internat. Rev. Agr. Econ., 8 (1917), No. 2, pp. 41-49).—The working features of the State hall insurance act of North Dakota, providing State insurance for "growing grain crops in any county in the State against loss or damage by hail," are described. Balance sheets showing financial conditions are appended.

Possibilities of a market-train service, G. C. White and T. F. Powell (U. S. Dept. Agr. Yearbook 1916, pp. 477-487).—In this article several market trains in operation are described. The authors take the position that this form of service, where practicable, affords an excellent method of restoring the custom of direct dealing between producer and consumer. "Such a service, to be successful, depends on the organized effort of the producing community, intelligently directed in sympathetic cooperation with the carrier."

A system of accounts for cotton warehouses, R. L. Newton and J. R. Humphrey (U. S. Dept. Agr. Bul. 520 (1917), pp. 81).—The system outlined requires twelve forms, which are described and illustrated.

Essentials in larger food production, C. G. HOPKINS (Illinois Sta. Circ. 197 (1917), pp. 4).—This is an address given before a conference of Illinois mayors April 27, 1917.

The author believes that the two factors of primary importance are sufficient labor to perform the necessary farm work and sufficient soil fertility to make

the larger crop yields possible. He advocates the erection in every town of a storehouse for ground limestone and phosphate rock, to be kept on hand ready for farmers to haul and apply whenever the conditions of the roads and fields and farm labor permit.

The high cost of low crop yields.—Intensive cultivation most profitable on average farms, C. E. Thorne (Mo. Bul. Ohio Sta., 2 (1917), No. 6, pp. 181–187).—Experiments using a 10-acre tract, fertilized, limed, and treated with acid phosphate were compared with larger unfertilized tracts of a size to produce about the same yield. A regular rotation of corn, oats, wheat, and clover was followed at Wooster, and one of corn, wheat, and clover at Germantown.

The relative costs of producing the entire rotation were \$613 and \$1,095 for the high and low-yielding tracts at Wooster, and of \$271 and \$396.10 for those at Germantown. It is concluded that "the intelligent use of fertilizer and manure not only increases the yield of the land but also reduces both the labor cost per unit of crop production and the cost of seed and rental."

The net output from agriculture and its distribution, C. S. Orwin (Jour. Bd. Agr. [London], 24 (1917), No. 2, pp. 158-161).—Tabulated results of surveys of several farms indicate that the net output, the difference between cost of production and value on the farm, is distributed to the farmer, laborer, and landlord on the basis of 47.9, 29.9, and 22.2 per cent, respectively. Net returns, however, after the farmer and landlord have deducted ordinary expenses, are found to be distributed on the basis of 40.7, 39.5, and 19.8 per cent, respectively.

Agriculture on Government reclamation projects, C. S. Scoffeld and F. D. Farrell (U. S. Dept. Agr. Yearbook 1916, pp. 177-198, pls. 3).—The purpose of this paper is "to discuss briefly a number of the industries that have been or may become important on reclamation projects."

The authors find that crop production on reclaimed land follows a "regular sequence of development, beginning with the production of alfalfa and small grains and gradually reaching a great diversity of crops and industries. Finally, out of this diversity a few major industries became permanent."

Crop disposal is said to constitute a more serious problem than that of production.

The sugar-beet industry, potato production, seed production, cotton production, fruit production, pork production, dairying, the sheep industry, and beef production are among the phases discussed.

British agriculture the nation's opportunity, E. G. Strutt, L. Scott, and G. H. Roberts (London: John Murray, 1917, pp. XI+168).—This book, after a review of English agricultural policy and problems of land settlement before the war, consists of a discussion of the findings and recommendations of the minority report of the departmental committee on the employment of sailors and soldiers on the land referred to in a previous note (E. S. R., 35, p. 296).

[Progress of agriculture in India] (*Rpt. Prog. Agr. India*, 1915–16, pp. 84–89).—Such forms of agricultural cooperation as societies for the sale of manure, cooperative dairies, cattle breeding societies, registered seed unions, and cattle insurance societies are briefly mentioned. Various recommendations and tendencies are discussed.

A graphic summary of world agriculture, V. C. Finch, O. E. Baker, and R. G. Hainsworth (U. S. Dept. Agr. Yearbook 1916, pp. 531-553, figs. 19).—Production and acreage of important crops are compared for the important countries of the world. Several page maps indicate graphically crop and acreage comparisons.

Price Current Grain Reporter Yearbook, 1917, E. G. OSMAN (*Price Current Grain Rptr. Yearbook 1917*, pp. 96).—This issue continues data previously noted (E. S. R., 35, p. 893), giving statistics for a later year.

# AGRICULTURAL EDUCATION.

[Agricultural and home economics instruction at the National Education Association in 1916] (Addresses and Proc. Nat. Ed. Assoc., 54 (1916), pp. XII+1112, figs. 10).—This report contains the papers presented at the 1916 meeting previously noted (E. S. R., 35, p. 197), and in addition the following papers relating to agriculture and home economics: First Aid to the Country Teacher-A Suggestion as to Vitalizing the Country Schools through Our Present Teachers [by means of instruction in gardening, poultry raising, and domestic science for girls], by J. D. Eggleston (pp. 58-63); Mass Instruction through Group Training [illustrated by the home-demonstration work in the Southern States], by O. B. Martin (pp. 97-101); Preparing Teachers for Leadership in All Special Education, J. W. Crabtree (pp. 122-127); Thrift in Its Relation to Country Life, by R. H. Wilson (pp. 201-205); The Conservation of Natural Resources through Education, by L. W. Goldrich (pp. 722-726); The Teaching of Home Nursing and the Care of Children to Elementary and High-school Pupils, by Isabel M. Stewart (pp. 767-771); and Vacation-club Work, by J. H. Beveridge (pp. 1060-1063).

State higher educational institutions of North Dakota (U. S. Bur. Ed. Bul. 27 (1916), pp. 204, figs. 26).—This is a report to the North Dakota State Board of Regents of a survey made under the direction of the U. S. Commissioner of Education. A very detailed report is given on the legal provisions for the establishment of the North Dakota Agricultural College, its organization, functions, finances, etc. Among the recommendations of the survey committee are the following:

The agricultural college should devote its energies and means to instruction in agriculture and its immediate allied subjects, offer courses in liberal arts and sciences only as service courses, and give no degrees therein. Agricultural, industrial, and chemical engineering courses should be given only at the agricultural college, and degree courses in other forms of engineering only at the university.

While the university should prepare high school teachers, school superintendents, supervisors for both elementary and high schools, and expert special teachers, the agricultural college only should prepare special teachers of agriculture, home economics, and industrial subjects. The latter should offer both major and normal courses in home economics, while the university should give sufficient instruction in this subject and in methods of teaching it to fit young women for the duties of intelligent home making, and to enable them to combine the teaching of home economics with other subjects in the high school.

The agricultural high school at the agricultural college should be discontinued as a preparatory school, and the 22-week courses strengthened and organized into a school of agriculture, elementary mechanic arts and home economics, with 3-year winter sessions of five and one-half or six months each, for young men and women who do not expect to attend cliege or to become teachers. The short winter courses in extension work for farmers and farmers' wives are to be commended, but those attending these courses should not be taught in the regular classes of the college, the agricultural high school, or the 22-week courses.

In view of the liberal Federal and State provision for extension work in agriculture and home economics under the direction of the agricultural college, no other institution in the State should undertake extension work in these subjects. Any extension work done by instructors in agricultural schools in the State should be under the direction of the college.

Graduate work at the university and the agricultural college should for the present continue to be limited to the requirements for the master's degree,

and each institution should give graduate instruction only in its major subjects. Graduate courses in education may be given at each institution.

The president of the agricultural college should have general control of the experiment station and of its branches and of the extension department, and be held responsible to the board of regents for their management. Men and women engaged in research work at the experiment station at Fargo should, except in case of those whose duties are such as to make it inexpedient, be expected to teach some classes in the college, and the experiment station and its farms and laboratories, as well as the laboratories of the regulatory services, should be used under necessary restrictions as teaching agencies for undergraduate college students and as research agencies for graduate students. It is recommended that a careful study be made of the operations of the substations and demonstration farms, with a view to determining whether or not much of the experimental work now under way might be carried on by farmers on their own premises without other expense to the State than that of necessary supervision.

The forestry and nursery work required of the school of forestry at Bottineau should be put under the direction of the agricultural college and all necessary instruction of college grade in forestry given at Fargo.

A survey of educational institutions of the State of Washington (U. S. Bur. Ed. Bul. 26 (1916), pp. 228, figs. 46).—This is a report of a survey made under the direction of the U. S. Commissioner of Education, at the request of the commission of educational survey created by the State legislature, of the State institutions of higher education, and such a study of the elementary and secondary schools and of the preparation of teachers in these schools as was deemed necessary to an intelligent consideration of the functions and standards of the higher schools. A report of the findings and recommendations of the commission of educational survey, as submitted to the governor, is included. Subsequent action of the legislature has been previously noted (E. S. R., 36, p. 296).

Agricultural instruction.—The Central Development Farm, Weraroa, F. S. Pope (Jour. Agr. [New Zeal.], 14 (1917), No. 2, pp. 83-88).—The author briefly discusses the defects in existing schemes of agricultural education and development in New Zealand, and the objects of the Central Development Farm (operated until recently as the Weraroa Experimental Farm), which is intended as the main factor in a system to overcome these difficulties.

Report of the agricultural society of Malmöhus Province for 1916 (Malmö. Lüns. Hushåll. Sällsk. Kvrtlsskr., 1916, No. 4, pp. VIII+505-928, figs. 2).—The activities of the society reported on include the work of the farm schools at Vilan, Fridhem, and Skurup, the dairy school at Näsbygård, the agricultural school at Dala, the home economics schools at Fridhem and Östra Grefrie, the dairy school at Alnarp, the fruit culture school at Apelryd, special courses in agriculture and home economics for adults and teachers, the seed-control station at Lund, the chemical station at Alnarp, the swine breeding stations, etc.

What is the Smith-Hughes bill providing Federal grants to vocational education? And what must a State do to take advantage of the Federal vocational education law? (Nat. Soc. Prom. Indus. Ed. Bul. 25 (1917), pp. 1-42).—This bulletin contains information as to the essential points of the Federal Aid Vocational Education Act (E. S. R., 36, p. 701) and of the steps the States should take to secure the benefits of the act; the text of the act; tables showing the Federal funds available for each State; principles and policies of vocational education as a means for the educational conservation of children; principles and policies that should underlie State legislation; and a form of bill, for enactment by a State accepting the act, framed and distributed by the Federal Board for Vocational Education.

The chemistry of farm practice, T. E. Keitt (New York: John Wiley & Sons, Inc., 1917, pp. XII+253, figs. 81).—This text, which has been prepared for high schools in farming communities, vocational and industrial schools, and short-course students in agricultural colleges, deals with the fundamental principles of chemistry and their application to the problems which arise in the life on a farm, including the study of soils, fertilizers, and manures, feeds and the calculation of rations, animal nutrition, milk and its products, sanitary water, boiler water, insecticides, fungicides and disinfectants, paints and whitewashes, materials producing heat and light, and concrete.

Nature study or stories in agriculture (Ontario Dept. Agr. Bul. 243 (1916), pp. 70, figs. 46).—This is a revised edition of the bulletin previously noted (E. S. R., 14, p. 822).

The culture of the mulberry silkworm, T. A. Keleher (Washington: Author, 1917, pp. 18, figs. 3).—This brief manual, adapted for practical use or for study in the classroom, gives instruction regarding the life history and rearing of silkworms as adapted to commercial puprsuits.

Vocational mathematics for girls, W. H. Dooley (Boston, New York, and Chicago: D. C. Heath & Co., 1917, pp. VI+369, figs. 79).—This text is offered as an introduction to the regular secondary school course in mathematics. It consists of six parts dealing respectively with a review of arithmetic; problems in home making, including the distribution of income, food, construction of a house, cost of furnishing a house, and thrift and investment; problems in dressmaking and millinery; office and store problems; arithmetic for nurses; and problems on the farm. An exposition of the metric system, graphs, formulas, and useful mechanical information are appended.

Live-stock classifications at county fairs, S. H. RAY (U. S. Dept. Agr., Farmers' Bul. 822 (1917), pp. 12, fig. 1).—This discusses, in a general way and with reference to increasing the educational value of the county live-stock exhibit, cooperation with live-stock organizations; uniformity of classification; special features, such as futurity and judging contests; selection of superintendents, judges, etc.; arrangement of exhibits; announcement of judges, prize winners, etc.; exhibition of prize winners; rules governing an exhibition; premiums; and a suggested scheme of classifications.

Illustrated lecture on public-road improvement (U. S. Dept. Agr., States Relat. Serv. Syllabus 29 (1917), pp. 12).—This syllabus has been prepared in the Office of Public Roads and Rural Engineering. It considers only the general features of public-road improvement, including the three distinct phases of public sentiment, finance, and engineering entering into most road problems. Points to be studied in the location and design of roads to balance the convenience of travelers against the question of economy, types of surface, and maintenance are discussed. A list of 56 lantern slides to illustrate the syllabus is appended.

[School home gardening] (U. S. Dept. Int., Bur. Ed., School Home-Gard. Circs., 1917, No. 12, pp. 13; 1916, No. 13, pp. 5; 1917, Nos. 14, pp. 4; 15, pp. 4; 16, pp. 3).—The following subjects are dealt with in these circulars: School home garden results of 1916, mainly in those cities that are cooperating with the U. S. Bureau of Education in working out the plan for school-directed home gardening; garden projects in seed planting; flower growing for school children in elementary grades; the part played by the root in the production of a crop; and home gardening for town children.

The effect of home-demonstration work on the community and the county in the South, B. Knapp and Mary E. Creswell (U. S. Dept. Agr. Yearbook 1916, pp. 251-266, pls. 3).—The authors describe the home-demonstration work for women and girls in eight counties of the South and some of the benefits

resulting. "This work began in 1910 with the girls' canning clubs, and led by gradual and logical steps into the present very broad and comprehensive work with both individuals and groups. In the fall of 1916 home-demonstration work was in progress in 420 counties in the southern States."

#### MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1916 (U. S. Dept. Agr. Yearbook, 1916, pp. 783, pls. 97, figs. 74).—This contains the report of the Secretary of Agriculture, previously noted (E. S. R., 37, p. 297); 33 special articles abstracted elsewhere in this issue; and an appendix containing a directory of the agricultural colleges and experiment stations and the State officials in charge of agricultural and extension work, and statistics of the principal crops, farm animals and their products, the Federal meat inspection, estimated value of farm products, tonnage carried on railways, 1913–1915, imports and exports of agricultural products, rural and agricultural populations, number of persons engaged in agriculture and area of agricultural land in various countries, and the utilization of the National Forests,

Annual report of the director of the experiment station on work done under the local experiment law in 1916, J. F. Duggar (Alabama Col. Sta. Circ. 35 (1917), pp. 35).—This includes a report by the director on the progress of the work under this law (E. S. R., 24, p. 400), a financial statement for the year, and reports from heads of departments, including detailed reports of boys' and girls' club work and other extension activities.

Twenty-ninth Annual Report of Colorado Station, 1916 (Colorado Sta. Rpt. 1916, pp. 39, fig. 1).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1916, a report of the director on the work and publications of the station, and departmental reports.

Twenty-ninth Annual Report of Louisiana Stations, 1916, W. R. Dodson (Louisiana Stas. Rpt. 1916, pp. 29).—This contains the organization list, a report by the director including brief departmental reports, and a financial statement as to the Federal funds for the fiscal year ended June 30, 1916, and as to the State funds for the fiscal year ended November 30, 1916. The experimental work reported is for the most part abstracted elsewhere in this issue.

Twenty-eighth Annual Report of Maryland Station, 1915 (Maryland Sta. Rpt. 1915, pp. XXX+214, pls. 9, figs. 50).—This contains the organization list; a report by the director on the organization, work, and publications of the station; a financial statement for the fiscal year ended June 30, 1915; and reprints of Bulletins 185–190, previously noted.

Twenty-ninth Annual Report of Maryland Station, 1916 (Maryland Sta. Rpt. 1916, pp. XII+95, figs. 16).—Data corresponding to the above are given for the fiscal year ended June 30, 1916, including reprints of Bulletins 191-196, previously noted.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 2 (1917), No. 6, pp. 171-209, figs. 8).—This contains several articles abstracted elsewhere in this issue, together with the following: Handling Alfalfa Hay, by J. W. Ames and G. E. Boltz, an extract from Bulletin 247 (E. S. R., 29, p. 32); The Currant Worm, by W. H. Goodwin; The Colorado Potato Beetle, by H. A. Gossard; and notes.

Monthly bulletin of the Western Washington Substation (Washington Sta., West. Wash. Sta. Mo. Bul., 5 (1917), No. 3, pp. 29-44, figs. 8).—This number contains brief articles on the following subjects: Second Crops for Milk and Meat, by H. L. Blanchard; The Root Maggot Pest, by E. B. Stookey (see p. 566); A Dairy Farm Plant, by I. D. Charlton (see p. 591); Weeding Out the Poor Producers, by Mr. and Mrs. G. R. Shoup; and Home Canning, by T. J. Newbill.

## NOTES.

California University.—Dr. C. H. Shattuck, whose resignation as head of the department of forestry at the University of Idaho has been previously noted, has accepted an appointment as professor of forestry.

Delaware College and Station.—Recent appointments include R. V. Mitchell, of the New Hampshire College, as professor of poultry husbandry, vice H. V. Cory resigned to become captain in the National Army; R. W. Goss as associate plant pathologist; and H. T. King as assistant chemist in the station, vice L. W. Tarr.

Iowa College.—A special short course has been arranged to begin November 12 and continue until about April 1, 1918. This course will include instruction in agriculture, home economics, engineering, and industrial science, and will be open to young people who have not yet completed high-school work, as well as to those prepared for full collegiate instruction.

Minnesota Station.—Andrew Boss has been appointed vice director in addition to his present duties. R. P. Ingram resigned as seed inspector in the division of plant pathology and botany July 31. Miss Mildreth J. Haggard has been appointed chemist in animal nutrition beginning September 1, and Miss Anna Wuentz, graduate assistant in entomology, beginning January 1, 1918. J. J. Willaman has been promoted from assistant chemist to plant chemist.

Mississippi Station.—The large breeding barn was struck by lightning July 26, and was completely destroyed together with two other barns located near by and some farm machinery and other equipment. The total loss was between \$15,000 and \$18,000.

Nebraska University.—Dr. A. R. Davis, assistant professor of agricultural botany, has been commissioned captain in the Coast Artillery.

Cornell University and Station.—The trustees have voted to pay members of the staff who enter war service the difference in salary between the army wage and that previously received.

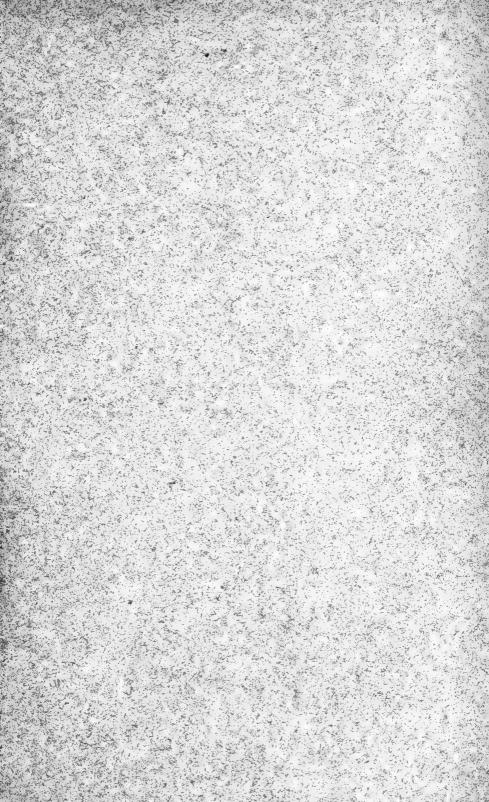

South Carolina Station.—A class of 15 scouts received training in the botanical laboratories during the first two weeks in September, preliminary to taking up survey work in the South for the Plant Disease Survey of the U. S. Department of Agriculture. Leon H. Leonian has been appointed research assistant in horticulture.

Tennessee University and Station.—The bond issue of \$1,000,000 voted by the last legislature for the university has been sold and it is expected that the money will be immediately available. Among the first expenditures was an allotment for barns and laborers' cottages on the new Cherokee Farm donated to the university for station purposes.

Texas Station.—P. V. Ewing, of the Georgia Station, has been appointed animal husbandman in swine investigations and has entered upon his duties. Wellington T. Brink, a 1916 graduate of the Kansas College and engaged in newspaper work, has been appointed technical assistant to the director, in charge of the station library, and editor of publications.

Utah Station.—H. P. Anderson, assistant chemist and bacteriologist, has resigned to become instructor in agriculture in the Price High School and local leader of boys' club work. O. P. Madsen has resigned as assistant poultryman to become county agent in Emery County. Yeppa Lund and Harold Goldthorpe have been appointed assistants in the department of chemistry and bacteriology.

## EXPERIMENT STATION RECORD.

Vol. 37.

November, 1917.

No. 7.

The thirty-first annual convention of the Association of American Agricultural Colleges and Experiment Stations, held in Washington, D. C., November 14-16, seems likely to be long remembered as one of the most interesting and inspiring in the history of the organization. As was pointed out by Secretary Houston in his address of greeting, according to the calendar barely a year had gone by since the previous meeting, but "judged by the experiences through which we have passed, it has seemed more like a generation." The profound changes during this period which the entrance of the Nation into the war has brought to every institution represented were reflected in the program, the point of view, and the predominating spirit of the convention.

Official delegates were in attendance from every State in the Union, as well as Porto Rico, and a delegation was also present from Canada which was given the privileges of the floor. From many institutions there were representatives for each of the five divisions of college, station, extension, engineering, and home economics work. The total registration of delegates and visitors aggregated three hundred and seventy, surpassing all previous records.

The large attendance was the more noteworthy since the number of other organizations meeting with the association was somewhat smaller than in 1916. Prior to the opening of the convention itself, a four-day conference was held of State leaders of home demonstration agents and the States Relations Service. The Society for the Promotion of Agricultural Science, the American Society of Agronomy, the National Potato Association, the American Association for the Advancement of Agricultural Teaching, the American Association of Farmers' Institute Workers, and the Association of Official Agricultural Chemists also held sessions before or after the convention. The attendance at many of these meetings was likewise unusually large, and while many of their papers followed the usual scientific and technical lines a distinctly war-time flavor permeated their programs and proceedings.

The program of the Association of American Agricultural Colleges and Experiment Stations naturally gave primary consideration to questions associated with the war and its relations to the land-grant institutions. The presidential address, for example, was entitled The Morrill Act Institutions and the New Epoch. It considered some of the far-reaching changes which the war is bringing to the Nation, and the responsibilities and opportunities of these institutions not only during the conflict itself but in the era to follow.

In this address President Butterfield outlined some of the ideals of the democracy for which the Nation is contending, such as real equality of opportunity, the exaltation of manhood and of the religious motive, and the substitution of cooperation for coercion. He indicated that the Nation would look to the agricultural colleges for their full share of leadership in bringing these ideals to realization. As he brought out, this will mean far more than the training of experts to increase production, important as this will continue to be. Its aim will be to develop leaders, men and women broadly educated and with vision and sympathetic understanding of what the new democracy will represent in rural life. As a preliminary step to meet the changing conditions, President Butterfield suggested the appointment of a national agricultural committee to consider the whole rural situation as affected by the war.

Practically an entire afternoon was deveted to a discussion of food and food administration, with addresses by Hon. Herbert C. Hoover, director of the Federal Food Administration; Prof. Isabel Bevier, of Illinois: Dean Catharine J. MacKay, of Iowa; and President C, R. Van Hise, of Wisconsin. The address of Secretary Houston, already referred to, discussed the season's work in food production and similar needs of the future. The experiment station section devoted its entire attention to this topic, with papers by Dr. Graham Lusk, entitled Calories in Common Life, this being mainly a discussion of the economic use of foods on the basis of their energy values, and a symposium on what the stations can most profitably do to increase the efficiency of food production and conservation in the present national emergency, participated in by Dr. Raymond Pearl, of Maine; Dr. E. W. Allen, of the Office of Experiment Stations; and others. From a somewhat different point of view the home-economics division took up the food-conservation program in a joint session with the conference of home-demonstration agents, Dr. A. E. Taylor, of the Food Administration, discussing the necessity and purpose of food conservation, and others, representing the Food Administration and the States Relations Service, describing the past summer's work and projected plans for the future.

An economic study of the farmer's income as affected by war conditions was presented at one of the general sessions by Prof. T. N. Carver, of Harvard University, in which he considered in detail various items of income and outgo during the past season. Wide variations were found in the net profits accruing from different types of farming, ranging from losses on many dairy farms in the Northeastern States, where much grain is purchased, to profits somewhat larger than the average in sections where little or no fertilizer is required and the primary staple crops are marketed. The duty to the Nation at this time of conserving profits, however reasonable or legitimately acquired, was strongly emphasized.

Special mention should also be made of the stirring speech of President G. C. Creelman, of the Ontario Agricultural College, on Canada's part in the war. Some of the remarkable accomplishments of Canada, particularly that of materially increasing wheat produc-

Special mention should also be made of the stirring speech of President G. C. Creelman, of the Ontario Agricultural College, on Canada's part in the war. Some of the remarkable accomplishments of Canada, particularly that of materially increasing wheat production despite the wholesale withdrawal of labor to make up an army as large in proportion to population as would be one of 5,000,000 men from the United States, were impressively narrated, and tribute paid to the substantial aid being rendered by the Canadian agricultural colleges and experiment stations.

The important service of the land-grant institutions in this country was attested by several speakers. Thus Secretary Houston declared that while at the time the country entered the war the Nation was not fully prepared for war in any respect "it was fortunately circumstanced in the character of its agricultural organization and the number and efficiency of its expert agencies. In fact, in efficient machinery for directing agricultural activity as represented by the land-grant colleges, the Federal Department of Agriculture, farmers' organizations, and its alert and patriotic rural population, it excelled any other two or three nations in the world combined."

"The Nation may well pride itself," he said, "on the fact that it had had the foresight generations ago to lay deep its agricultural foundations." He congratulated the representatives of the landgrant colleges on the fine opportunity for service presented to them and on the splendid way in which they had seized it. "The Department of Agriculture has had great comfort in the thought that these institutions, ably planned and wisely directed, existed in every part of the Nation and stood ready not only to place themselves at the service of the National Government but also to take the initiative in a vast number of directions."

Similarly, President E. C. Perisho, of South Dakota, in a paper before the college section on The Best Things Done by the Land-

grant Colleges to Meet the War Emergencies of the Nation, maintained that "no portion of our people responded more quickly or more intelligently than did the men and women of the land-grant colleges. From every one of these institutions there was sent at once to State and Federal authorities not only assurance of loyalty but the free offer of men, military departments, laboratories, machine shops, experiment plats, engineering plants, agricultural workers, and the entire staff of our extension divisions." This service took the form of cooperation with State and Federal governments, assistance in the production and conservation of food materials, the work of the extension divisions and experiment stations, aid rendered along military lines, the offering of special emergency courses, and many forms of individual aid by students, faculty, and alumni.

Appreciation of the part played by the land-grant institutions along military lines was voiced by Major Clark, representing the Adjutant-General's Office of the War Department, who specially commended the work of the men entering the officers' training camps; and by President James of the University of Illinois, who drew attention to some of the potentialities of these institutions as military assets. Maj. David S. White, of the Veterinary Corps of the U. S. Army, in a discussion of the organization and workings of this branch of the service, indicated the substantial aid rendered by many institutions in supplying competent veterinarians.

Interest in past achievements of the colleges and stations, however, was far overshadowed by the evidence of their desire to serve the Nation in the most effective way possible in its present and future needs. The program was, therefore, constructive rather than reminiscent, and dealt quite largely with ways and means for immediate application. For example, in addition to papers already referred to, President Soule, of Georgia, took up in the college section the question of how the land-grant colleges may be organized to serve the Government in the war emergency, and the engineering and home economics divisions considered modifications in their respective curricula to meet the emergency conditions.

As would be expected, special interest centered in the developments along the line of extension work. The Federal program for extension work during the war period was outlined by Dr. A. C. True. The program suggested for the agricultural colleges and the Department of Agriculture included as its principal items the full maintenance of the food supply and its conservation, the preservation of a permanent and safe system of agriculture, the rendering of assistance in the solution of such problems as farm labor and the handling and marketing of farm products, and assisting the Federal Government in spe-

cial work from time to time. Some of these phases were discussed by others in considerable detail.

For instance, President Pearson, of Iowa, took up the cooperation of the extension service with State councils of defense and other public and private organizations. Vice-director M. C. Burritt, of New York, and Director John T. Caine, of Utah, discussed forms of organization required in the county before funds are available for the employment of emergency food agents; and Director C. A. Keffer, of Tennessee, and Miss Florence E. Ward, of the States Relations Service, described the correlation of men and women agents. Under the general subject of Methods of Meeting the Farm Labor Shortage, Director C. W. Pugsley, of Nebraska, discussed the Organization of Farm Labor Bureaus, and Director William D. Hurd, of Massachusetts, the Utilization of Nonproductive or Partially Nonproductive Labor, such as the boys' working reserve and similar agencies.

An important problem as regards extension publications was referred to in the report of the bibliographer, which dealt with agricultural literature and the war. The vitally significant change in the character of this literature during the year has been, as Dr. True stated, the tremendous output of popular emergency material of a new sort, "exhortation and precept cast into pictorial, mimeographed, or printed form, bulletins, posters, circular letters, and what not." This material has been distinguished alike "by its endless variety in form of presentation and its endless repetition of subject matter."

Much of the duplication has been of course unavoidable under the circumstances, but as Dr. True maintained, "the situation no longer justifies the same degree of duplication of effort or breathless haste of issue and distribution. It is now possible to foresee, for a sufficiently extended period, the subjects which will claim attention, and it will, therefore, be possible carefully and thoughtfully to plan for the advantageous use of existing and available material, as well as for the preparation of such new matter as may be needed. The variety in form and subject of what has been issued gives ample opportunity for matured, well-considered selection of suitable forms of presentation, and will be valuable as a guide to the formulation of more definite principles by which future activities may be guided."

The discussion of the part which the experiment stations should play in the war program has already been referred to. Interest in this topic was decidedly keen, and the strong desire of station workers to bring their work into close relations with the emergency conditions was much in evidence. It was recognized that the fundamental character of the stations as research institutions must be

preserved, but there was general concurrence in the view expressed that "the emergency presents special reason for some degree of temporary adaptation and less rigid adherence to strict limitations and the pursuit of established projects than under normal conditions."

Numerous specific suggestions were made as to how this redirection of effort could be accomplished. The situation may be summarized by the following quotation from one of the addresses: "The experiment stations can be of the greatest service at this time by continuing to serve in the capacity of experts in agricultural science and its interpretation, by supplying tested and reliable information and making this available and applicable, by expert study of the general situation in its relation to agricultural production, by supplying counsel and formulating broad plans and policies, by being alert to detect and act upon the present necessities, and by exercising foresight in preparing for post-bellum conditions. They can do this—

"(1) By letting their work be known—by seeing to it that it is

written up and published promptly.

"(2) By maintaining unusually close relations with the publicity and teaching agencies, seconding the efforts of the extension and other agencies in helping and protecting the producer.

"(3) By a revision of their project programs, selecting for special attention those having an emergency or present importance, and by adapting others so as to take account of the changed conditions resulting from the war.

"(4) By working close to the ground, reaching out into the State and maintaining an unusually close contact with the actual condi-

tions of production.

"(5) By inaugurating, to a limited extent naturally, new investi-

gations having war-time and post-bellum significance.

"(6) By working close together, either in cooperation or with mutual understanding, and at least with full recognition of other similar work, in order that greater accuracy may be attained and time economized."

Aside from war questions the convention had before it a number of other important matters. A development of the year which received special consideration was the enactment of the Federal Vocational Education Aid Act. Although this measure, as is well known, deals with instruction of subcollegiate grade and makes no direct reference to the land-grant institutions in its scheme of administration, its workings are none the less of great interest to them. One of the general sessions was largely devoted to this subject, and in

addition a round-table conference was held by the home economics division on the training of teachers in that subject. The topic likewise assumed great prominence in the meetings of the Association for the Advancement of Agricultural Teaching, with addresses by a member of the Federal Board for Vocational Education and several others of the staff.

At the general session of the association, some of the policies and plans of the Federal Board were outlined by Mr. Charles A. Prosser, director of vocational education, while some requisites in the training of teachers under the act were discussed for agriculture, the trades and industries, and home economics by the assistant directors for each of these subjects. Dean Alfred Vivian, chairman of the State Board of Education of Ohio, closed the discussion as spokesman from the points of view of the association and the State boards.

The address of Mr. Prosser drew attention to the large measure of authority given under the act to the State boards of vocational education in correlating the new system with the work of existing institutions, but he expressed the opinion that the land-grant colleges would render very useful service. The greatest needs in developing vocational education he considered to be intelligent supervision and a competent teaching force, and he maintained that the colleges, with their unique advantages as sources of subject matter, possess a special opportunity for developing strong courses to meet these needs.

A similar view as to the opportunity and duty of the agricultural colleges in teacher training was taken by the standing committee on instruction in agriculture in its report on college teaching in agriculture, with particular reference to the improvement of methods. In this report the committee expressed the view that "strong departments of agricultural education will be needed under the administration of the Smith-Hughes Act in order to give the colleges of agriculture the positions they should occupy in the training of teachers of agriculture. Unless these colleges take up the teacher training work actively at the present time, the funds provided for this work under the Smith-Hughes Act are likely in many States to be divided among a number of institutions, including some of relatively low grade and poor equipment, with the result that our whole system for training teachers of agriculture will be fundamentally weak. The agricultural colleges ought to have a clear leadership in this field, and they can not have this unless they adequately equip their departments of agricultural education."

The committee also urged the development of such departments as a means of improvement of college teaching in general. It was

recognized that in the past a large proportion of college graduates without special pedagogical training have done well as teachers, but, "they have succeeded in spite of the lack of professional training, and the percentage and degree of successes might have been much larger if the professional training had been provided. No matter how well manned and equipped the subject matter departments of the colleges of agriculture may be, they need the help of strong departments of agricultural education, not only in the training of undergraduates for teaching positions but also in improving the quality of teaching within the subject matter departments."

Two other papers of direct interest to educators were presented. One of these was a study of the prevailing requirements for graduation in agriculture in the land-grant colleges, presented before the college section by Dr. C. D. Jarvis of the U. S. Bureau of Education. The second was a discussion of the status of agricultural engineering instruction in the land-grant colleges, by Dean Stout of Nebraska.

In Dr. Jarvis' study, a decided increase was noted in the entrance requirements for college work in agriculture within recent years, coupled with greater uniformity among institutions and considerable optional substitution of vocational for academic subjects. Much difficulty was found, however, in comparing the requirements for graduation, mainly because of the diversity of practice as to units of credit. Wide variations were also encountered in subject matter, its distribution by courses, proportion and kind of prescribed and elective work, and similar matters. The study made it apparent that there is still much difference of opinion as to the optimum college course in agriculture, although the discussion following its presentation indicated general agreement on the part of those present that as much uniformity should be obtained as would be feasible under varying conditions.

The report of the committee on college organization and policy was in two sections. The first section dealt with administrative organization, presenting fourteen recommendations for consideration. Under the plan proposed, the individual specialist capable of working independently is regarded as the unit of organization. A subject matter department would consist of the group of working specialists on that subject, regardless of the kind of service, and authority for subject matter would be confined to this group of specialists, administrative control being limited to the amount and method of work. Administrative authority would be on the basis of kind of service, with the various kinds coordinated under a chief executive.

The remaining section of the committee's report, and likewise the report of the committee on extension organization and policy, dealt largely with the relations of the colleges to other agencies, such as

the Federal Board of Vocational Education, the Food Administration, and the emergency and other work of this Department. The executive committee of the association was instructed to represent the interests of the association in these matters. A request from the college committee that the executive committee report on the feasibility of the preparation of a history of the Morrill Acts and supplementary legislation was also adopted.

The committee on graduate study discussed the status of the Graduate School of Agriculture under the emergency conditions. In view of the altered situation it advised the postponement for another year of a decision as to continuing the school. This recommendation was accepted by the association.

The familiar question of the form and content of station publications was discussed from various points of view. A comprehensive report was submitted by the committee on experiment station organization and policy, which drew attention to the prevailing diversity in practice. More than a score of existing series of publications were enumerated, and it was stated that many of the individual series may "mean one thing at one station or at one time, but another thing at a different place and time."

To relieve some of the existing confusion, the committee suggested five series of publications as covering the usual needs. These include, besides technical papers published in scientific journals, regular bulletins designated as bulletins, research bulletins, regulatory bulletins, circulars, and the annual report. Of these the bulletins are for the general reader, and devoted primarily to the publication of such "results of the station's own work as appear to be important or directly useful or interesting to the serious student of practical agriculture, especially the farmer." Technical material should be given special distribution, either by publication in scientific journals or in regular or research bulletins, issued in limited editions. Circulars when deemed necessary would include, not the popular information now largely disseminated through extension series, but popular accounts of small pieces of work, matter too ephemeral in nature to appear in the bulletin series, preliminary announcements, popular editions of bulletins, and similar material. The annual report is regarded as an administrative document, and designed to be an epitome and permanent record of the station's progress during the vear.

As to subject matter, the thesis was laid down that, "the publications of an experiment station properly consist of accounts and records of its experiments and investigations and of their applications, leaving to other agencies the dissemination of general information and experience, propaganda, descriptions of farm devices,

methods in farming, etc." The committee also pointed out that any scheme for publishing will require some supervision, and suggested the desirability for providing in connection with the director's office some machinery for assuring systematic attention to manuscript and matter in course of publication.

A report on publications from a committee of the Agricultural Libraries section of the American Library Association was also received, and is to be included in the proceedings of the association. This report dealt more specifically with the details of distribution of the publications among libraries, and their most effective utilization.

Still another phase of the subject was touched upon in the report of the association's committee on the publication of research, which again indicated very clearly some of the advantages accruing from the use of the Journal of Agricultural Research as a medium of publication. It was stated that of the one hundred and eleven papers appearing in the journal during the past year, fifty-seven were from station workers, representing twenty-four institutions.

The proposed initiation of Federal aid to research in engineering was again considered by the engineering section, and a compromise measure submitted by a committee of that section was subsequently approved by the association itself. This measure would provide \$15,000 per annum of Federal funds to each State and Territory for engineering experimentation at the land-grant college, but would involve an equal appropriation by the States for similar work to be conducted either at the same institution or elsewhere as determined by the legislature. The executive committee was instructed to urge the consideration of legislation along these lines as a war measure.

The election of officers resulted in the selection of Dean Eugene Davenport of Illinois as president; President C. A. Lory of Colorado, President A. M. Soule of Georgia, Director J. G. Lipman of New Jersey, President A. F. Woods of Maryland, and Dean R. W. Thatcher of Minnesota, vice presidents; and the reelection of the previous secretary-treasurer and bibliographer. The membership of the various committees underwent few changes. The vacancies caused by the retirement from land-grant college work of Presidents Waters of Kansas and Duniway of Wyoming were filled respectively by the appointment of Prof. G. A. Works of Cornell University to the committee on instruction in agriculture and President C. A. Lory of Colorado to the committee on college organization and policy. President W. M. Riggs of South Carolina succeeded President Waters on the executive committee, the personnel of which was otherwise continued unchanged. An amendment to the constitution proposing the enlargement of the executive committee to six members, the additional member to be selected by the extension section, was offered for consideration at the next annual meeting.

The section officers included for college work and administration, President E. C. Perisho, of South Dakota, chairman, and President R. D. Hetzel, of New Hampshire, secretary; in the station section, Dean W. M. Jardine, of Kansas, chairman, Director W. P. Brooks, of Massachusetts, secretary, and Mr. W. H. Beal, of the States Relations Service, recording secretary; and in the extension section, Director C. R. Titlow, of West Virginia, chairman, Dean E. C. Johnson, of Kansas, secretary, and Mr. Bradford Knapp, of the States Relations Service, recording secretary. The engineering division elected President W. M. Riggs, of South Carolina, chairman, and Dean A. A. Potter, of Kansas, secretary; and the home economics section, Miss Isabel Bevier, of Illinois, chairman, and Miss Mary Sweeny, of Kentucky, secretary.

The 1917 convention was thus an unusually interesting gathering, quite different in many respects from any which had preceded it. It revealed how closely the war has been brought home to the landgrant institutions, depleting the faculty and student body, interrupting many well established projects, and compelling a redirecting of their entire program and point of view. More strongly, however, did it indicate how largely the Nation is relying on these institutions in the present emergency, and how important are the functions which are theirs to fulfill. It put this great body of public service institutions, already conspicuous for a season's successful endeavor, formally on record as enlisted for the war, and with their full resources mobilized in the national service.

## RECENT WORK IN AGRICULTURAL SCIENCE.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Isolation of cyanuric acid from soil, L. E. WISE and E. H. WALTERS (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 2, pp. 85-92, pl. 1).—The authors note the isolation of a nitrogenous compound from an Indiana soil whose identity with cyanuric acid prepared by heating urea with zinc chlorid was established. The largest amount of the acid isolated from any of several lots of 23 kg. of the Indiana soil was about 0.15 gm. Cyanuric acid was also isolated from a Maine soil, 46 kg. of soil yielding about 0.165 gm. of acid; a Florida soil, yielding approximately 0.04 gm. of acid from 23 kg. of soil; and a Texas soil, which yielded about 0.04 gm. from 46 kg. of soil.

The procedure used in the isolation of the acid from the soil samples and the identification tests are described in detail. The possibility of the formation of cyanuric acid in the soil by the decomposition of nucleoprotein or purin bases, some of which have been previously isolated, and its possible derivation from urea are suggested.

Analysis of ragweed pollen, F. W. Heyl (Jour. Amer. Chem. Soc., 39 (1917), No. 7, pp. 1470-1476).—The following percentage composition is reported for the pollen of the ragweed (Ambrosia artemisifolia): Alcohol-soluble material, 42.9; moisture, 5.3; crude fiber, 12.2; pentosans, 7.3; ash, 5.4; dextrin, 2.1; and protein, 24.4. Of the protein about 7.5 per cent could not be extracted, while 6.75 per cent was extracted with dilute alkali and only about 5 per cent with 10 per cent salt solution. The albumin and globulin fractions thus appear to be small. The presence of proteoses is indicated. The alcoholic extract was found to have the following percentage composition: Fat, 10.8; lecithin, 0.75; ethersoluble (but not soluble in ligroin), 1.75; sucrose, 0.4; glucose, 1.6; resin, 17.4; and a nitrogenous base.

Some ophthalmic tests obtained in the case of two hay-fever subjects are noted.

The pungent principles of ginger.—I, A new ketone, zingiberone, occurring in ginger, H. Nomura (Sci. Rpts. Tohoku Imp. Univ., ser. 1, 6 (1917), No. 1, pp. 41-52).—The author notes the isolation from ginger of a ketone, zingiberone, having the composition  $C_{11}H_{14}O_{5}$ . The experimental procedures used in this isolation and the determination of its chemical constitution are described in detail.

Gingerol and paradol, E. K. Nelson (Jour. Amer. Chem. Soc., 39 (1917), No. 7, pp. 1466-1469).

Microorganisms and heat production in silage fermentation, O. W. HUNTER (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 2, pp. 75-83, figs. 10).— In the study reported by the author at the Kansas Experiment Station an endeavor was made to determine the exact cause of heat production in silage fermentation. Alfalfa, corn, cane, and Kafir corn forage, siloed under laboratory conditions, were used for silage production. Heat production was observed in normal fermenting forage, forage treated with a weak antiseptic, forage

treated with heat, heated forage inoculated with bacteria, and cured or dried forage. Normal check fermentations were provided by siloing untreated forage.

The untreated and inoculated forage all showed a marked increase in acid production, while the chloroformed and heated samples exhibited no increase. "Good clean-flavored silage resulted in every instance from the fermentation of the untreated, green, cured, and inoculated forage. The treated forage, that saturated with chloroform and that heated, exhibited no characteristics of silage." Heat production was observed only in the untreated and inoculated forage, with no indication of heating in any of the treated samples. The heat production of the different kinds of silage is represented in graphical charts.

From the investigation it is concluded that "heat production in forage fermentation results from microbial activity and not from intramolecular respiration of the tissue cells."

The citric acid fermentation of Aspergillus niger, J. N. Currie (Jour. Biol. Chem., \$1 (1917), No. 1, pp. 15-37, pls. 2, figs. 2).—The author has studied the inorganic salt requirements, the general equation of metabolism, and the reaction of the medium of the citric acid fermentation of A. niger. From observations of a large number of cultures, iron is not considered necessary for the development of spores. It is suggested, however, that some definite chemical reaction involved in the utilization of nitrates is accelerated in the presence of iron.

The fermentation of a sugar by A. niger is considered an oxidation proceeding in three stages and producing citric acid, oxalic acid, and carbon dioxid. The proportion in which the products of the metabolism appear can be varied at will. Quite different results are given by cultures, even under the same conditions, which can not be distinguished morphologically. By proper selection of cultures and conditions the yield of citric acid can be varied from none at all to over 50 per cent of the sugar consumed. Low nitrogen supply, high concentration of sugar, and nitrogen supplied as ammonium salts rather than as nitrates are conditions especially favorable to the fermentation. Where the nitrogen was supplied as ammonium salts or as asparagin, iron was not found to stimulate the metabolic processes in any way. In the case of nitrates the stimulating effect of iron, however, was especially noticeable in the increased production of carbon dioxid and weight of mycelium.

From the general consideration of the data obtained the following medium is considered the most suitable for conducting the citric acid fermentation with A. miger: Per 1,000 cc. of solution, saccharose 125 to 150 gm., NH<sub>4</sub>NO<sub>4</sub> 2 to 2.5 gm., KH<sub>4</sub>PO<sub>4</sub> 0.75 to 1 gm., MgSO<sub>4</sub>.7H<sub>2</sub>O 0.2 to 0.25 gm., HCl to  $P_{\rm H}$  3.4-3.5 (5-4 cc. fifth-normal).

Influence of certain electrolytes upon the course of the hydrolysis of starch by malt amylase, H. C. Sherman and Jennie A. Walker (Jour. Amer. Chem. Soc., 39 (1917), No. 7, pp. 1476-1493, figs. 7).—The rate of formation of reducing sugar by the action of purified malt amylase on soluble starch, both in neutral solution and in solution with the addition of regulated amounts of hydrochloric or phosphoric acids or primary potassium phosphate, was investigated.

"When the activating electrolyte was added in such amount as to give optimum or nearly optimum concentration of hydrogen ion, the action of the enzym was increased not only in the earlier stages but throughout the entire range investigated. The greater the concentration of enzym the less the effect of the added electrolyte. . . . Throughout the first half of the hydrolysis, or up to a yield of half the theoretical amount of maltose, the rate of maltose formation from soluble starch was found to be proportional to the concentration of substrate, at least in solutions containing favorable amounts of acid or acid

phosphate. When, in similar experiments, enzym concentration is varied within limits suitable for such quantitative study, the rate of maltose formation is found to be directly proportional to the enzym concentration up to a yield of about half the theoretical amount of maltose. This broadens the range within which diastatic activities may be compared quantitatively."

No "region of linear relationship" in which the yield of reducing sugar is directly proportional to the time was found. No cessation of hydrolysis nor true equilibrium at 80 per cent was shown in experiments with widely varied enzym concentration, as was claimed by some previous investigators.

A noteworthy effect of bromids upon the action of malt amylase, A. W. Thomas (Jour. Amer. Chem. Soc., 39 (1917), No. 7, pp. 1501-1503, fig. 1).—In an investigation on the activation of malt amylase by acids and salts it was observed that bromids when present in small amounts exercised an inhibitory effect on the action, but an activating action was observed when the concentration of the salt was increased. As previously shown, the chlorid, nitrate, sulphate, and phosphate of sodium and potassium activated malt amylase proportionately to the concentration of the salt present. The experiments were repeated with sodium and potassium bromid which had been recrystallized several times, positive results being obtained.

Experimental data are submitted in tabular and graphical form.

A handbook of organic analysis, H. T. Clarke (London: Edward Arnold, 1916, 2. ed., pp. VIII+263, figs. 23).—The subject is treated under the topics of preliminary investigation, examination for radicles, separation of organic compounds, quantitative determination of constituent elements, quantitative determination of radicles, and determination of some physical properties.

Classified tables which give the melting or boiling points and common reactions of the more common organic compounds are included. A detailed index of the tables is appended.

A titration flask, F. K. Bezzenberger (Jour. Amer. Chem. Soc., 39 (1917), No. 7, p. 1321, fig. 1).—A titrating flask, to be used in place of the weighing burette, which has been found to possess some advantages in volumetric analyses is described.

The estimation of sulphur in plant material and soil, G. A. Olson (Washington Sta. Bul. 145 (1917), pp. 3-12, figs. 2).—Tabular analytical data relative to the sulphur content of linseed meal, corn, peas, beans, wheat, casein, and gluten obtained by the Parr bomb calorimeter method and compared with the official and Osborne methods show that with certain precautions the bomb method can be successfully used without sacrificing any degree of accuracy for speed. The material should be very finely ground, the silica removed, and the precipitate of barium sulphate well washed.

For the determination of sulphur in plant materials a charge of 0.687 gm. was found to be the most satisfactory. The fusion mixture used was the same as that recommended by Parr, except that sodium nitrate was substituted for potassium nitrate because of the tendency of potassium salts to form double salts with barium. The mixture consisted of boric acid 5, sodium nitrate 3, and magnesium metal 1 parts by weight. The exact amount of sodium peroxid necessary was found to vary with the nature of the material, approximately 16 gm. being necessary for gluten and similar nitrogenous substances, while for starchy substances, such as flour, etc., from 12 to 14 gm. was found sufficient. Shortening of the electrodes about \{ \frac{1}{2} \) in. in the Parr bomb apparatus was found to be more satisfactory with the quantity of material used in the charges. A bomb having a bottom cast in one piece with the shell is considered preferable to one with a removable bottom.

For the determination of sulphur in soil a 2-gm, charge with 1 gm, of fusion mixture was used. In addition 0.5 gm, of sugar was added and from 10 to 12 gm, of sodium peroxid. Some slight precautions were found necessary in the application of the method to sulphur determination in soil. The method as adopted is described in detail.

The successful use of the bomb method for the determination of phosphoric acid is noted, but because of the easier manipulation of other procedures it is not considered desirable.

The influence of the presence of calcium carbonate on the determination of available phosphoric acid in soils by Dyer's method, Jatindra Nath Sen (Agr. Jour. India, 12 (1917), No. 2, pp. 258-265).—Some experimental data on the effect of large amounts of calcium carbonate in soils on the amount of phosphoric acid extracted by treatment with 1 per cent citric acid are submitted and discussed. Other factors which might affect the rate of solution, such as fineness of soil, composition, etc., are also discussed.

The retarding influence of calcium carbonate was considered not to be solely due to neutralization of citric acid, since the fall in the amount of phosphoric acid extracted was maintained up to a calcium carbonate content of 20 per cent when only 7.1 gm. of calcium carbonate was required to neutralize the citric acid used in the extraction. It thus appears that the phosphoric acid is actually absorbed or "fixed" from the solution by the calcium carbonate.

Phosphoric acid determination in phosphate rock, C. C. Semple (Engin. and Min. Jour., 103 (1917), No. 26, pp. 1140, 1141).—On account of the difficulty of obtaining molybdic acid the following procedure was devised for the determination of phosphoric acid in phosphate rock:

A 0.5-gm. sample of material containing 20 per cent or more phosphoric acid (or a proportionate sample of material containing less) is treated in a 75-cc. casserole with 10 cc. concentrated nitric acid and stirred until all the material is moistened and effervescence ceases. Twenty cc. of concentrated hydrochloric acid is then added and the material gently boiled on the hot plate. If soluble silicates are present they should be dehydrated by evaporating the material to dryness several times with concentrated hydrochloric acid.

The material is finally taken up with 10 cc. concentrated hydrochloric acid and boiled for a few minutes to dissolve all soluble salts. Boiling water is then added and the material allowed to set until the residue settles, after which the bulk of the solution is decanted on a filter and the filtrate received in a 300-cc. beaker. The residue in the casserole is again treated with concentrated hydrochloric acid and hot water, and finally transferred to the filter and washed with boiling water until the bulk of the filtrate is about 175 to 200 cc.

Ammonium hydroxid, a little at a time, is then added to the filtrate until the gelatinous precipitate of calcium, iron, and aluminum phosphates begins to form, after which 30 cc. of ammonium hydroxid (specific gravity 0.9) is added and the liquid well stirred. Ten cc. of a saturated solution of citric acid is added and the solution stirred for two minutes. Enough citric acid should be added to insure complete solution of all the precipitated phosphates.

Thirty cc. of magnesium mixture is added and the beaker set aside to allow precipitation. It is indicated that, although complete precipitation has been obtained in 1.5 hours, it is advisable to allow at least 3 hours and to keep the filtrate for 24 hours to be certain that complete precipitation has taken place. After complete precipitation the liquid is decanted, the precipitate finally collected on a filter, and washed with the usual wash solution, consisting of ammonium hydroxid and ammonium nitrate. The filter and precipitate are then placed in a crucible, dried, ignited, and weighed as magnesium pyrophosphate.

Comparative analytical data with the molybdate method indicate the accuracy of the procedure.

Approximate results may be obtained at the time of adding the citric acid, since the amount of acid required is proportionate to the amount of phosphate present. A solution of citric acid standardized against a known sample is added to the solution containing the precipitates until it just clears. Results within from 0.5 to 1 per cent of those obtained by the regular procedure are secured.

For the determination of lime in a complete analysis of phosphate rock the following procedure is proposed: A 0.5-gm. sample is treated in the same manner as in the phosphoric acid determination. The acid is entirely boiled off and the residue dehydrated. Hydrochloric acid is again added and the material heated to dryness. Fifteen cc. of concentrated hydrochloric acid is finally added and the material boiled, after which 50 cc. of boiling water is added and the material filtered and washed.

Since iron can not be separated from the filtrate by the addition of ammonia, because of the precipitation of calcium phosphate, ammonia is added until the precipitate begins to appear, and then hydrochloric acid, drop by drop, until the filtrate is clear again. Two cc. of hydrochloric acid is added in excess, the liquid heated to boiling, and 5 gm. of crystallized oxalic acid added, and, after solution, 40 cc. of boiling saturated solution of ammonium oxalate. After boiling for 30 minutes the precipitate is filtered, washed, ignited, and weighed as CaO, or dissolved in sulphuric acid and titrated with standard permanganate. The presence of the free oxalic acid keeps the iron in solution.

The use of fused quartz and alundum crucibles in place of platinum crucibles in phosphate work was found satisfactory.

Directions for preparing magnesium mixture and the wash solution are included.

Determination of carbonates in limestone and other materials, J. F. BARKER (New York State Sta. Tech. Bul. 62 (1917), pp. 3-7, fig. 1).—An apparatus which depends on the principle of the hydrometer and its manipulation are described.

In the apparatus the carbon dioxid is liberated from the material by dilute hydrochloric acid and the weight of the hydrometer decreased by the escaping gas. The rise of the graduated tube above the water thus records the percentage of carbonates from which the carbon dioxid was liberated. The method requires no weighing or computation of results, since the latter are given by direct reading of the graduated scale.

Comparative analytical data with the standard method indicate the accuracy of the proposed procedure. Some notes on details of manipulation, composition of limestone, and application of the method are included.

A rapid method for the determination of water-soluble arsenic in lead arsenate, H. A. Scholz and P. J. Waldstein (Jour. Indus. and Engin. Chem., 9 (1917), No. 7, pp. 682, 683).—A procedure similar to that noted by Gray and Christie (E. S. R., 36, p. 715) is described, as follows:

Five-tenths gm. of the dried and pulverized sample or 1 gm. of paste is weighed into a 250-cc. volumetric flask. Two hundred cc. of recently boiled distilled water is added and the mixture vigorously boiled for 3 to 5 minutes, allowed to stand 10 or 15 minutes, cooled, made to volume, and filtered through a dry paper. Two hundred cc. of the clear filtrate is measured into a 500-cc. Erlenmeyer flask, a few crystals of potassium iodid and 7 cc. of concentrated sulphuric acid added, and the liquid then boiled down to about 50 cc. It is then diluted with cold water, made alkaline to methyl orange with sodium hydroxid.

acidified with dilute sulphuric acid, and an excess of sodium bicarbonate added. It is then titrated with twentieth-normal iodin solution.

Experimental data submitted indicate closely agreeing or somewhat higher results by the proposed procedure when checked against official methods.

The inadequacy of the ferric basic acetate test for acetates, L. J. CURTMAN and B. R. Harris (Jour. Amer. Chem. Soc., 39 (1917), No. 7, pp. 1315-1317).—Data are reported which show that the ferric basic acetate test is not sufficiently sensitive and that it does not furnish a means of roughly estimating the amount of acetate present in a solution.

Gluten, M. Arpin (Liverpool: Offices of "Milling," 1917, pp. 23, figs. 5).— This is a translation, together with some notes, by W. Jago of the official French method for the estimation of gluten. Some notes on the interpretation of the results of the analysis of flours are also included.

The determination of pentoses and of glutose by means of Fehling's solution, H. Pellet (Internat. Sugar Jour., 19 (1917), No. 222, pp. 275, 276).—The reduction of Fehling's solution by pentoses (arabinose and xylose) and by glutose is discussed.

The importance of treating the sample with Fehling's solution at from 63 to 65° C, and maintaining it at such a temperature for 10 minutes in the determination of reducing sugars in impure samples which may not contain either pentoses or glutose is emphasized. In products supposed to contain either pentoses or glutose the heating should be continued for 30 minutes, or else at boiling temperature for 3 or 4 minutes.

It is indicated that "the organic matter of beet molasses behaves much less actively toward Fehling's solution than that contained in cane molasses."

The quantitative estimation of dextrose in muscular tissue, R. Hoagland (Jour. Biol. Chem., 31 (1917), No. 1, pp. 67-77).—On account of the reducing action on Fehling's solution, creatinin was found to be an important source of error in the determination of dextrose in muscular tissue. For the removal of creatinin and also as an efficient precipitant for other nitrogenous constituents of muscular tissue, an excess of phosphotungstic acid was found to yield excellent results. After considerable preliminary work the following method, which has yielded accurate results, was devised:

One hundred gm. of finely ground muscular tissue previously freed from visible fat and connective tissue is treated in a 600-cc. beaker with 200 cc. of distilled water, gradually heated to boiling, and boiled for a few minutes. During the extractions the contents of the beaker must be frequently stirred. After boiling, the insoluble material is allowed to settle and the clear liquid decanted on to the previously prepared asbestos filter in a 4-in. funnel. Filtration is carried on by the aid of suction. The residue is again extracted with 150 cc. of hot distilled water as above. The operation is repeated and the residue finally transferred to the filter, washed with hot water, and filtered as dry as possible.

The contents of the filter flask are transferred to an 800-cc. beaker and concentrated on the steam bath to a volume of about 25 to 30 cc. The concentrated liquid is then transferred to a 100-cc. volumetric flask, but the volume should not be allowed to exceed 60 to 70 cc. It is cooled to room temperature, from 25 to 30 gm. of phosphotungstic acid dissolved in about 25 cc. of water added, shaken thoroughly, and let stand for a short time. The solution is then made to volume, shaken, and either filtered or centrifugalized to remove the solid matter. The use of the centrifuge is preferable. A portion of the filtrate is tested for complete precipitation by the addition of dried phosphotungstic acid. If an appreciable precipitate forms, an aliquot portion of the

filtrate should be taken, treated with an excess of dry phosphotungstic acid, made to volume, filtered, and the filtrate tested for complete precipitation.

When the precipitation is complete sufficient dry potassium chlorid is added to precipitate the excess of phosphotungstic acid. The potassium phosphotungstate is filtered off and the filtrate tested for the presence of creatinin. When an appreciable excess of phosphotungstic acid has been used for clarification not more than a trace of creatinin should be found. The sugar is then determined in aliquot portions of 25 cc. of the filtrate by Allihn's method and the reduced copper by Low's iodid method.

In view of the reported increased formation of dextrose in muscular tissue during grinding for analysis, it is suggested that when the dextrose content of the sample is to be determined immediately after the death of the animal the weighed sample be cut into several pieces, plunged into boiling water, and the boiling continued for from five to ten minutes. The clear liquid should then be decanted, the residue ground in a meat grinder, and the extraction carried out as usual.

Determination of sugar in hay and turnips, R. K. Kristensen (Tidsskr. Planteavl, 23 (1916), No. 5, pp. 757-777).—Continuing previous work (E. S. R., 36, p. 807), it has been found that either water or alcohol can be satisfactorily used for extraction of the sugar in the materials. For cruciferous plants alcohol extracts have been found to yield the most reliable results. Basic lead acetate could not be used for clarifying the solutions, but mercuric nitrate was entirely satisfactory, and its use is recommended. The reduction of the precipitated cuprous oxid to metallic copper is considered not to be necessary unless the solution has not been clarified by some defecating agent.

Determination of the alkalinity and phosphoric acid content of foodstuffs, I. M. Kolthoff (Chem. Weekbl., 14 (1917), No. 24, pp. 547-558).—This is a discussion of the comparative merits of the author's method (E. S. R., 36, p. 204) and the method of Pfyl, which depends on precipitating the phosphates as tricalcium phosphate with calcium chlorid and titrating the liberated hydrochloric acid with standard alkali, using phenolphthalein as an indicator, after converting the phosphates into primary phosphates. Some comparative analytical data obtained in the examination of pure solutions and the ash of bread, pepper, and milk powder by the above methods and the procedure of Lorenz (E. S. R., 13, p. 14) are submitted.

It is concluded in general that the method of Pfyl does not possess any advantages over the method previously proposed by the author.

Specifications and directions for testing milk and cream for butter fat, O. F. Hunziker (Jour. Dairy Sci., 1 (1917), No. 1, pp. 38-44).—This is a report of the data on official methods of testing milk and cream for milk fat submitted at the Official Dairy Instructors' Association meeting held at Springfield, Mass., October 16 and 17, 1916 (E. S. R., 35, p. 799).

The Shrewsbury and Knapp process for the estimation of coconut oil, G. D. Elsbon and C. R. Bagshawe (Analyst, 42 (1917), No. 492, pp. 72-83, figs. 2).—
The authors have studied the method previously noted (E. S. R., 24, p. 515) and have found that the most suitable strength of alcohol to use is of specific gravity 0.92 at 15.5° C. With alcohol of this strength concordant results could be obtained with mixtures of coconut oil and butter and coconut oil and margarin containing up to about 60 to 65 per cent coconut oil. With mixtures containing greater percentages of coconut oil the results obtained were not so satisfactory. Where the samples contained 70 per cent or more of coconut oil, alcohol of specific gravity 0.91 was found to yield satisfactory results.

Washing the fatty acids once with 50 cc. of cold water was found to be sufficient.

It is indicated that the filtration should be carried out as nearly as possible at 15.5°. Cooling the alcoholic solution to about 14° and violently shaking before bringing to the final temperature of 15.5° has been found to yield more concordant results.

The modified procedure is described in detail and experimental data obtained in the examination of mixtures containing coconut oil submitted.

Observations and experiments on the preparation of tea, J. J. B. Deuss (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 52 (1917), pp. 34, pl. 1).—This pamphlet discusses the withering and fermentation of tea and gives results of some experiments on artificial and natural drying of tea. The data are submitted in tabular and graphical form.

## METEOROLOGY.

Forecasting the seasons, A. McAde (Sci. Amer. Sup., 84 (1917), No. 2169, pp. 50, 51, figs. 2).—This article briefly discusses the so-called Réseau Mondial, or world net, in its relation to the forecasting of seasonal conditions on the basis of the position of infrabars and hyperbars. It is shown that the survey thus provided makes possible certain important deductions regarding the control of seasonal conditions by the large pressure areas. The article also deals with the relation of sun spots, volcanic eruptions, and heavy cannonading to weather changes.

It is stated that "we may dismiss the question of the effect of war in making unseasonable weather; but we can not disregard the rather more important question—the effect of an abnormal season upon the operations of man, including war. An unseasonable continuance of south and east winds over central Europe due to a temporary displacement of the continental infrabar may cause deficient rainfall if not drought during the growing period and so affect the harvests."

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 4 (1917), Nos. 3, pp. 250, pls. 3, figs. 8; 4, pp. 217, pls. 3, figs. 3).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for March and April, 1917, respectively.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostbander and W. P. Saunders (Massachusetts Sta. Met. Buls. 341-342 (1917), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1917, are presented. The data are briefly discussed in general notes on the weather of each month.

The meteorology of Brazil, C. M. Delgado de Carvalho (Météorologie du Brésil. London: John Bale, Sons, & Danielsson, Ltd., 1917, pp. XIX+528, pls. 12, figs. 34; rev. in Scot. Geogr. Mag., 33 (1917), No. 7, pp. 315-325).—This is in the main a compilation of the principal things that have been published about the climates of Brazil, with numerous references to sources of information. It includes sections of special interest from the standpoint of agricultural meteorology, as, for example, droughts and measures taken to mitigate them; frost; and the weather conditions prevailing in the regions especially adapted to coffee, cacao, and sugar cane.

Three groups of climates are recognized, "(1) equatorial and subequatorial climates, which include those of the region extending to the latitude of the lower São Francisco, about 11° S.; (2) tropical and subtropical climates, em-

bracing the greater part of the remaining area within the Tropic of Capricorn; and (3) temperate climates—that is, practically those of the four southern States of Brazil, beginning on the coast with Santos, just outside of the Tropic, but extending in the higher interior 2 or 3 degrees north of that line. These groups are then subdivided into regions in accordance with the rainfall and humidity, altitude, and situation with respect to the ocean, and under each of these the climates of minor regions are studied with reference to selected typical stations. The first group is divided into the superhumid or Amazonian type, and the semiarid or northeast Brazilian type; the second, into the semihumid type of the middle latitudes, and the semihumid altitude type."

It is stated that droughts are more often due to irregular and badly distributed rainfall than to actual deficiency. One of the peculiarities of farming in the drier areas of northeastern Brazil is the use of artificial reservoirs (acudes) "dotted over the surface, not for the supply of irrigation water to be led to adjacent fields, but merely to allow of the marginal tracts of silt exposed after floods being cultivated during the dry season. The topography of large parts of this region is such that the lowering of the water surface in one of these reservoirs by the evaporation of 5 ft. in depth of water is enough to expose immense tracts of cultivable ooze."

The weather conditions, especially distribution of the rainfall, of the plateau of São Paulo are peculiarly suited to the growth of coffee. The fact that Brazilian coffee has suffered so little comparatively from diseases is attributable to the favorable weather conditions.

As regards cacao, humidity is a more important climatic requirement than temperature, since this plant is especially susceptible to injury from drought.

It is noted that among the essential climatic requirements for sugar cane is an abundance of rain. In the Campos region, where sugar cane is principally grown, there is sufficient rainfall during two or three months to make conditions exceptionally favorable for the growth of this crop. There are, however, occasional dry years, which are seriously injurious unless irrigation is freely practiced. The irregularity of the precipitation in this region is shown by the fact that during the 20 years, 1888 to 1907, the total annual rainfall varied from 8 to 95 in.

Frosts are very irregular in occurrence and distribution and do not form a constant phenomenon at any given place.

A classified bibliography is given.

The rainfall régime of Indo China, G. Le Cadet (Bul. Écon. Indochine, n. ser., 20 (1917), No. 123, pp. 1-50, pls. 4).—Tables and charts are given which show the mean rainfall and number of rain days per month and per year, as well as the extremes of such data, at stations well distributed throughout the country, for periods varying from five to ten years. The characteristic features of the rainfall of the region as shown by the data are discussed, as well as certain features of the relation of the amount and distribution of rainfall to plant growth.

The average annual rainfall shown by the data reported appears to be about 1,800 mm., varying widely, however, in different years and localities. The number of rain days averages over 100. Attention is called especially to the greater plant response to freshly fallen rain due to its higher radioactivity.

Dissolved oxygen in rain water, E. H. RICHAEDS (Jour. Agr. Sci. [England], 8 (1917), No. 3, pp. 331-337, flgs. 2).—Reference is made to the importance of dissolved oxygen in rain water as one of the chief factors controlling bacterial activity in soil, particularly in relation to the decomposition of organic matter. Previous investigations on the subject are briefly reviewed, and the results of a

year's observations at Rothamsted on the dissolved oxygen content of rainfall are reported and discussed, with descriptions of the apparatus and methods used.

The results show that rain water is very nearly saturated with oxygen when the temperature of collection is below 15° C., but is always below saturation, occasionally as much as 25 per cent, when the temperature is above 15°.

The coefficient of correlation, W. G. Reed (Quart. Pubs. Amer. Statis. Assoc., n. ser., 15 (1917), No. 118, pp. 670-684, figs. 4).—The limitations and applicability of the coefficient of correlation as a measure of relationships, as, for example, between July rainfall and yield of corn in Ohio, are discussed.

"The coefficient of correlation is obtained by applying the least square adjustment to all the material and is, therefore, the straight line of closest fit. If the relationship is not that of a straight line, it is obvious that the straight line of closest fit is not a good measure of the relationhip and that some other measure (e. g., the correlation ratio) must be used. Therefore, the coefficient of correlation should never be used to show relationship until after the phenomena have been investigated, at least far enough to show whether a straight line satisfies the relationship as well as any other curve."

The method of procedure to be followed in applying the method is explained in some detail, and a bibliography of the subject is given.

### SOILS—FERTILIZERS.

Soil survey of Barbour County, Ala., H. C. SMITH, N. E. BELL, and J. F. STROUD (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1914, pp. 50, fig. 1, map 1).—This survey, made in cooperation with the State of Alabama, deals with the soils of an area of 579,840 acres in southeastern Alabama, the topography of which ranges from hilly and broken to nearly level. The drainage is well developed.

The area is included in the coastal plain province, and the soils are classed as upland, stream terrace, and bottom-land soils. Including meadow, 23 soil types of 13 series are mapped, of which the Ruston sandy loam, Norfolk sand, and Ruston gravelly sandy loam cover 21.3, 14.3, and 10 per cent of the area, respectively.

Soil survey of Chickasaw County, Miss., E. M. Jones, C. S. Waldbop, and H. H. Bennett (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1915, pp. 58, flg. 1, map 1).—This survey, made in cooperation with the State of Mississippi, deals with the soils of an area of 320,640 acres in northeastern Mississippi, the topography of which ranges from level or undulating to rolling or hilly. Except in the Flatwoods section the drainage system of the county is well developed.

The upland soils derived from coastal plain deposits cover over three-fourths of the area. The alluvial soils of the overflowed stream bottoms consist mainly of silt and clay. Including chalk and rough gullied land, 24 soil types of 14 series are mapped, of which the Lufkin silt loam, Oktibbeha clay, Ruston fine sandy loam, and Lufkin clay cover 9.6, 9, 8.6, and 8.1 per cent of the area, respectively.

Soil survey of Anson County, N. C., E. S. VANATTA and F. N. McDowell (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1915, pp. 65, pls. 7, figs. 2, map 1).—This survey, made in cooperation with the North Carolina Department of Agriculture, deals with the soils of an area of 344,960 acres in central southern North Carolina, which lies on the boundary between the Coastal Plain and the Piedmont Plateau provinces. The topography is undulating to hilly.

"The county is thoroughly dissected by streams, and there are no large upland areas without natural drainage outlets. While there are many flat areas and depressions, in both the uplands and bottoms, which are naturally poorly drained, there is a much larger area from which the water flows off so rapidly as to cause severe erosion."

The soils of the county are of residual, sedimentary, and alluvial origin. Twenty-eight soil types of 13 series are mapped, of which the Georgeville silt loam and the Cecil gravelly loam cover 11.2 and 10.5 per cent of the area, respectively.

Analyses of soils of the Belgian Kongo by the physiological method, F. SMEYERS (Bul. Agr. Congo Belge, 7 (1916), No. 3-4, pp. 268-284, figs. 13).—Pot experiments are reported with oats, white mustard, and barley to determine the fertility requirements of seven typical soils of the lower Belgian Kongo, including black, dry, and tenacious lowland soil, fine-grained sandy soil, calcareous prairie soil, alluvial clay soil, brown clay forest soil, upland soil with lateritic subsoil, and upland sandy soil. The surface soils were tested to a depth of about 30 cm. (11.81 in.). Fertilizer treatment consisted of complete fertilization and of complete fertilization without nitrogen, phosphoric acid, potash, and lime, respectively.

The results indicate that the soils of the lower Kongo are generally deficient in nitrogen, this being the limiting factor. The addition of the other fertilizing elements without nitrogen had no appreciable effect on the vegetation. The fine-grained sandy soil and the upland sandy soil were the only soils tested showing a notable deficiency in phosphoric acid, while the upland sandy and brown clay forest soils were the only soils not somewhat deficient in potash. The fine-grained sandy soil was the only soil seriously deficient in lime.

The wheat soils of Alexandria division, Cape Province, C. F. JURITZ (So. African Jour. Sci., 13 (1917), No. 6, pp. 211-237).—Mechanical and chemical analyses of 10 cultivated and 10 virgin soils are reported and compared with similar analyses of wheat soils in the United States and England. Deterioration was observed for some years in the crops from these soils, especially wheat.

"Mechanical analysis showed the soils to range in physical character from medium sands to fine sandy loams, the proportions of very fine sand, silt, and clay together varying between 16 and 63 per cent, while pebbles, gravel, and coarse sand were practically absent. . . . The causes of inadequate production, therefore, seem to be (1) the rather sandy character of some of the soils, conjoined with their inherent poverty in plant-food constituents; (2) the removal of some of those constituents by continuous cropping without manure; and (3) the further losses caused by the surface soil suffering depletion in respect of silt and clay. The moisture conditions of the soil have not been investigated. Out of the 10 localities investigated only one is not in immediate need of manuring of any kind, in order to fit it for wheat production. Eight require manuring with nitrogen, five need potash fertilizers, and six need fertilizing with phosphates."

Some soils of the southern island of New Zealand with special reference to their lime requirements, L. J. Wild (Jour. Agr. Sci. [England], 8 (1917), No. 2, pp. 154-177, figs. 2).—Studies of the lime requirements of certain New Zealand soils, including so-called shingly inland soils, deep loams underlain by deep clay, and alluvial soils resting on gravel and in river beds, using the Hutchinson-MacLennan method (E. S. R., 33, p. 622), are reported.

It was found that "the Hutchinson-MacLennan method for determining the lime requirements of soils, when practiced under suitable standard conditions, gives more reliable indications than are obtainable by the ordinary methods of chemical analysis. The method gives indications which appear to be uniformly

in excess of the actual requirement of the soil for lime as judged by economic standards; hence a correcting value seems advisable. The correcting value for the soils of Canterbury Plains is about 0.1 per cent. The greater acidity and higher lime requirement of soils of the Southland Plains appears to be due to a combination of lack of natural underdrainage and high rainfall, which prevents aeration and oxidation of organic matter, so that 'sour' humus accumulates in the soil."

Causes of acidity of soils which are acid through exchange of ions, H. KAPPEN (Landw. Vers. Stat., 89 (1916), pp. 39-80; abs. in Jour. Chem. Soc. [London], 110 (1916), No. 650, I, p. 876; Chem. Abs., 11 (1917), No. 8, p. 1008).— Experiments with two pine-forest soils and a soil on which the vegetation consisted of a few bilberry bushes are reported.

The forest soils, which were covered with a layer of humus from 2 to 3 cm. (0.79 to 1.18 in.) deep, showed considerable activity when treated with a normal solution of potassium chlorid, while the third soil failed to react. The latent activity of the forest soils is attributed to the action of humic acids on the mineral soil and the production of aluminum and iron salts. It is shown that the true acidity of humus extracts is approximately the same as that of acetic acid of the same strength, and that latent acidity can be produced by treating mineral soils with raw humus. The same result was obtained with only partially humified vegetable substances. It is also thought possible that latent acidity can arise from the production of soluble aluminum and iron compounds in the humus itself and the penetration of the soluble salts into the mineral soil below the humus.

Movement and distribution of moisture in the soil, F. S. Harris and H. W. Turpin (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 3, pp. 115-155, figs. 31).—Field and laboratory soil moisture experiments conducted at the Utah Experiment Station under irrigation and dry-farming conditions, and representing several thousand moisture determinations, are reported. The field studies included the effect of fallow, kind of crop, manure, irrigation water, surface mulches, cultural methods, and seasonal conditions on the movement and distribution of soil moisture. The laboratory studies included the effect of the initial percentage of moisture, gravity, soil type, source of supply, etc.

In field soils the moisture content of the fallow soils averaged greater than that of the cropped soils. Unmanured irrigated land showed less difference in moisture between cropped and fallow than did the manured. Irrigation influenced the top feet of the cropped plats proportionately more than the fallow, but water did not appear to penetrate the fallow plats below 7 ft. as readily as it did the cropped ones.

Under dry-farming conditions the difference in moisture between cropped and fallow plats was not noticeable until after June 16. Cropped plats showed more fluctuation than fallow ones. Wheat, corn, potatoes, and peas drew most of their moisture from the first 4 ft. in depth. The wheat land contained less moisture in the fall than the other cropped soils, with corn following.

The increase in moisture due to applications of from 5 to 7.5 in. of irrigation water was felt to depths of 10 ft. in 24 hours, although most of the increase was in the first 4 ft.

The effect of mulches in preventing moisture loss under both irrigation and dry farming was noticeable several feet below the surface of the ground, but the surface foot showed the greatest benefit from mulches. A straw mulch proved considerably better than a 2-in. soil mulch. Mulches on irrigated plats appeared to influence the moisture content of the soil to greater depths than did those under dry-land conditions. A dry-farm plat kept free from weeds in

1916 but not mulched lost very little more water than one mulched 2 in. deep. A 6-in. cultivation on spring-plowed and a 2-in. cultivation on fall-plowed dry-farm land seemed to conserve the moisture best.

Subsoiling 15 in. deep had little influence on the moisture; spring disking was a rather distinct benefit. Spring plowing under dry-farming conditions at Nephi conserved moisture better than fall plowing, this difference in favor of spring plowing being shown more below the first foot than in the first foot, and more in the summer and fall than in the spring.

A precipitation as small as 0.1 in. under dry-farming conditions could not be detected in moisture determinations soon after, but when as much as 0.5 in. fell within a short time an increase in moisture was noticed to a depth of 6 ft.

"When freely supplied with water, a soil with a high initial percentage of moisture will come to a moisture equilibrium sooner than a drier one, but if given time the drier soil will absorb a greater quantity through a long distance either upward or downward than will the wet one. The rate of moisture penetration in the first 10 days was nearly twice as great with initial percentages above 15 as with 5 or below, and nearly twice as rapid after a 15-in. irrigation as after a 5-in. one. Under the most favorable conditions 7 ft. was influenced in 10 days. Moisture movement from soils of optimum moisture content into soils of differing initial percentages varied to an extent inversely as the initial content of the dry soil. At the end of six weeks, however, the amount of water actually in the soils still varied directly as the initial percentage. The higher the percentage of moisture in the soil supplying the water to a dry soil, the more rapidly and farther from the source of water did the moisture move. Even when the source of water was an unsaturated soil, greater and faster movement took place when the water was moving downward When the quantity of soil yielding the water was so small as to make the total moisture content of both moist and dry soils very low if equally distributed, the effect of gravity was not great.

"Moisture from a nearly saturated soil moved a greater distance into loam than into sand in 189 days and into sand farther than into clay. The clay, however, contained more moisture in the layer of soil next the water supply than the others, and sand contained by far the least. Sand, with 7.77 per cent of moisture, gave up its moisture to loam much more readily than did loam with 31.09 or clay with 24.62 per cent of moisture. The rate of rise of moisture from soils of varying fineness when used either as water sources or water absorbers varied inversely with the fineness. Water rose to a height of over 30 in, in a loam soil from a moist sand in 94 days, while from a moist clay it rose little more than 6 in, in this length of time. In all soils the most rapid rise of the water was during the period soon after being placed in contact with the water. Although the rise of the moisture was more rapid in the sand and loam than in the clay, the rise continued steady longer in the clay than in the others."

Adsorption by soils, J. E. Harris (Jour. Phys. Chem., 21 (1917), No. 6, pp. 454-473).—Further experiments at the Michigan Experiment Station on the subject (E. S. R., 31, p. 814), using uniform samples of sandy loam soil, are reported. The purpose was to secure additional evidence that the cause of soil acidity is due to colloidal adsorption or to the presence of true acids, and to secure data on the action of fertilizer salts.

It was found that "when a soil or kaolin is treated with salt solutions of varying concentrations the quantities of the cation adsorbed follow very closely the adsorption isotherm represented by the equation  $x/m=ac^{1n}$ , indicating that the action is one of adsorption and not of double decomposition.

"When the soil was treated with different salt solutions it was found that the number of equivalents of the different cations adsorbed was not the same. The

cations with reference to their tendency for being adsorbed occurred in the order: Al, K, Ca, Mn, Mg, and Na. The numbers for the ions Ca, Mn, and Mg were very nearly the same. . . . The metals, with the exception of the potassium occur in the order of their valence and . . . metals of the same valence give practically the same values.

"It was found that a soil that had adsorbed large quantities of potassium would give part of this up when treated with various salt solutions. In the case of the solutions tried it was found that, with reference to their ability to set free adsorbed potassium, the salts occurred in the following order: AlCl<sub>5</sub>, NH<sub>4</sub>Cl, MnCl<sub>5</sub>, CaCl<sub>2</sub>, CaSO<sub>4</sub>, MgCl<sub>5</sub>, NaCl, CaCO<sub>5</sub>.

"When the soil was treated with a mixture of salts it was found that the amount of each ion adsorbed was cut down by the presence of the other. The total number of equivalents adsorbed from the mixture was greater, however, than from either of the salts alone."

Results of soil fertility studies, C. B. Williams (North Carolina Sta. Rpt. 1916, pp. 14-16).—Chemical and petrographic studies of the soils of North Carolina have shown that "wide variations in the total amount of the elements of plant food ... exist between the soils of the Appalachian Mountains, Piedmont plateau, and Atlantic coastal plain. The soils of the first physiographic province are better supplied with phosphoric acid, potash, and lime than are those of the other two provinces. . . . Those of the Piedmont plateau are, as a rule, amply supplied with potash and lime and with phosphoric acid in rather large amounts in some cases. On the other hand, the soils of the coastal plain south of Albemarle Sound are markedly deficient in all essential elements of plant growth. Nitrogen is usually low in a majority of the soils of all three sections of the State."

Petrographic studies of these soils correlate markedly with the chemical studies. Topography plays an important part in their chemical composition. Soils of the mountains are formed from the same or similar rock as are those of the Piedmont section, but in the mountains the soil mantle is not so well defined, consequently there are more of the minerals found in the parent rock when the superficial covering has been removed. The coastal plain soils are markedly deficient in minerals except quartz.

In coordinating these studies with the field tests, using various crops as indicators for measuring the relative densities of the soil solution, close relationships appear to exist between the chemical and mineral composition of the soils of each province and their requirements for plant nutrients. Nitrogen is either the first or second element required by all the soils under experiment.

Field tests with four distinct types of soil in the mountain sections, namely, Porter's clay, Porter's loam, Toxaway silty loam, and Toxaway loam, show that with all four types "phosphoric acid is needed first, and potash shows no gain with different crops, except where complete fertilizer is used and large crops produced. Lime alone shows gains on leguminous crops, and when used with complete fertilizer a gain is made. On Porter's clay and Porter's loam nitrogen is second in importance to phosphoric acid, and has to be supplied to produce good crops. Toxaway loam and Toxaway silty loam need nitrogen for best results, but not so much as the upland mountain soils to produce remunerative crops."

Field tests of Piedmont soils, Cecil clay near Charlotte, Cecil clay loam near Statesville, and Cecil sandy loam near Gastonia, all show phosphoric acid to be the limiting constituent of plant food, with nitrogen second. Very little benefit is derived from potash, except where used in a complete fertilizer. The tests on the Iredell loam near Charlotte show that nitrogen is the first element of plant food needed, with potash and lime next. Although a complete fertilizer

with lime gives best returns where phosphoric acid alone is used, no increase is secured. Alamance silt loam near Monroe, Durham sandy loam near Oxford, and Norfolk coarse sand near Hoffman all show nitrogen to be the most needed element of plant food, with phosphoric acid and potash, giving good yields when used with phosphoric acid and nitrogen. For large crops a good supply of all of the plant food constituents with lime is needed, as well as an increased supply of vegetable matter. On the Cecil clay soils potash either gives no gain or depresses the yields. On other phases of the Cecil series of soils experiments show that nitrogen is the chief limiting element of plant food for large yields of crops, with additions of phosphoric acid needed for best crops. Potash is of least importance.

Field tests with coastal plain soils show that "with the exception of muck, nitrogen is the limiting element of plant food, . . . with potash and phosphoric acid needed to produce good gains in crop yields. The results on Norfolk sandy loam at Elizabeth City have shown that phosphoric acid comes before potash in importance. . . On the muck soil, lime seems to be of first importance, [followed in order by] . . . phosphoric acid, potash, and nitrogen. . . . Nitrogen, potash, and phosphoric acid give best returns when used in connection with lime. Norfolk sand at Greenville gives evidence of needing humus-forming material before any fertilizer can be used with profit. With peaty soils, the addition of potash and phosphoric acid seems to have a depressing effect so far when used alone or in combinations without lime."

Thirty-five years' results with fertilizers, F. D. GARDNER, C. F. NOLL, and P. S. Baker (*Pennsylvania Sta. Bul. 146 (1917)*, pp. 3-29, figs. 11).—This is a summary of the results of experiments begun in 1881 and previously noted (E. S. R., 34, p. 128) on the use of commercial fertilizers, barnyard manure, lime and land plaster in a rotation of corn, oats, wheat, and mixed clover and timothy grown on residual limestone soil varying from clay to silt loam in character.

It was found that in the absence of manure or fertilizers of any kind the fertility of this soil showed a marked decline. The average yield of all crops in the rotation for all of the untreated plats during the last five years was only 61 per cent as much as the yield for the same plats and crops during the first five years. The reduction in yield was most pronounced in case of hay and corn. Wheat started with a comparatively low yield and showed the smallest decline in yield. The average yield of both wheat and wheat straw during the last five years equaled 94 per cent of the yield during the first five years.

"Phosphoric acid is the limiting factor in crop production on this soil. The average yield on the plats treated with phosphoric acid alone is 18 per cent more than the average of the check plats and 41 per cent more than the average of check plats which are nearest to the phosphoric acid treated plat. Ground bone as a source of phosphoric acid appears to be slightly more efficient than dissolved bone black."

Potash alone had no appreciable effect on the yield of crops, but potash applied with phosphoric acid gave a very marked increase in yield over phosphoric acid alone, and very materially increased the profits on the fertilizer applied. The use of 100 lbs. of muriate of potash per acre in alternate years is believed to be sufficient to meet the needs for the crops grown on this soil. Potash and phosphoric acid in combination proved to be the most profitable mixture used. This combination in this rotation, in which clover occurs once every four years, practically maintained the fertility of the soil for a period of 35 years.

Nitrogen alone and a combination of nitrogen and potash had no appreciable effect on these crops. Nitrogen in addition to phosphoric acid and potash produced a considerable increase in yield of crops. Of the three forms of nitrogen,

sodium nitrate gave a larger average increase in crops than either dried blood or ammonium sulphate. During the first ten years of the experiment, ammonium sulphate was superior to either sodium nitrate or dried blood, but later the yields declined and crops began to fail on the ammonium sulphate plats.

None of the plats used in this comparison of sources of nitrogen have been limed since the experiment was begun. "On the plats where the heaviest applications of sulphate of ammonia have been made there are large areas where all crops fail. This we believe is due to the acidity of the soil, especially since in pot cultures, when soil from these most acid plats was limed, the yields of clover were excellent. . . . The nitrate of soda plats are least acid, and the crop yields are probably not reduced by a lack of lime. On some of the dried blood plats the acidity has become too great for a good growth of clover though other crops do not show signs of injury."

Complete commercial fertilizers, except where ammonium sulphate was used, and barnyard manure were about equally efficient in maintaining the fertility of the soil. The heavier applications of each caused the yields during the last five or ten year periods to exceed those of the first five or ten year periods of the experiment.

Manure applied in different amounts showed that there is economy in light applications when used for general farm crops. The money return per ton of manure, when applied at the rate of 6 tons per acre twice in a rotation, was \$3.29 as compared with \$2.29 per ton when applied at the rate of 10 tons per acre twice in the rotation.

Lime either as slaked lime or as carbonate of lime applied alone in large amounts frequently gave a small increase in yields of crops. Burnt lime alone during a period of 35 years gave an average increase of 701 lbs. of total products per acre in a rotation, as compared with the untreated plats immediately adjacent. Pulverized raw limestone under the same conditions gave an average increase of 1,334 lbs. of total products in a rotation, as compared with untreated plats nearest to the pulverized limestone plats. The larger return from burnt lime was where it was used in conjunction with barnyard manure. In this case there was an increase of 1,001 lbs. of produce per acre in a rotation valued at \$6.38. Land plaster or gypsum had no measurable effect on the crops grown and did not prevent the soil from becoming acid.

"For the limestone soils of Pennsylvania it is recommended that manure be applied at the rate of about 6 tons per acre for corn, and supplemented with 200 lbs. per acre of acid phosphate. For oats which follow the corn, no fertilizer will be required. For the wheat which follows oats, 350 lbs. per acre of acid phosphate, 100 lbs. of muriate of potash, and not more than 10 lbs. of nitrogen, preferably in an organic form, is recommended. For the clover following wheat, no fertilizer will be required. On timothy occurring the fifth year in a rotation, a top-dressing of 150 lbs. of acid phosphate, 150 lbs. of nitrate of soda, and 50 lbs. of muriate of potash will give good results."

Injurious effect of farmyard manure on the balance of nitrogen in the soil, A. Sabashnikov (Sabachnikov) (Selsk. Khoz. i Liesov., 250 (1916), Jan., pp. 5-19; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, pp. 802, 803; Chem. Abs., 11 (1917), No. 9, p. 1242).—The chief influence of barnyard manure on the balance of nitrogen in the soil is attributed to the organic matter it contains and not to microorganisms, which are considered of secondary importance. The organic matter in the manure (especially undecomposed straw), being a good source of carbon for the soil microorganisms, contributes (1) in an aerobic environment to the assimilation of nitrates, ammonia, amids, and gaseous nitrogen, and their deposition in protein

form; and (2) in an anaerobic environment in the presence of nitrate to the assimilation of the latter, and also on the other hand to its denitrification.

The nitrogen in barnyard manure is considered to be chiefly in an organic form and its loss in the gaseous state is thought to be possible without its passing into the nitric state, both in the aerobic and anaerobic environment. The organic matter, contributing to the conversion of the protein nitrogen, indirectly promotes the loss of nitrogen in further decomposition. A local retardation in furrows, etc., of the nitrifying processes is also possible owing to the organic matter, to the presence of which the nitrifying organisms are known to be very sensitive.

As to the question whether barnyard manure supplied to the soil in quantities up to 28 tons per acre reduces nitrification or not, it is thought that a negative conclusion can not be drawn. It is considered possible that the presence of vegetable residues in the soil and the continuous conversion of nitrogen from the soluble form into the organic form or vice versa may cause such heavy losses of nitrogen (although compensated by its assimilation from the air) that the effect of the additional organic matter in the form of barnyard manure is relatively unimportant.

[Manure conservation experiments], C. D. Woods (Maine Sta. Bul. 260 (1917), pp. 94-99).—An experiment on the storage of cow, horse, hog, and sheep manure during the winter is reported, in which an account was kept of all feed eaten and the manure was stored in a water-tight platform (which is described) and kept worked by swine to prevent fire fanging. The composition of the mixture of cow, horse, and hog manure as removed from the pit was nitrogen 0.457 per cent, phosphoric acid 0.19, and potash 0.5. The sheep manure contained nitrogen 0.74 per cent, phosphoric acid 0.29, and potash 1.04. "Seventy-nine per cent of the nitrogen, 87 per cent of the phosphoric acid, and 87 per cent of the potash in the feeding stuffs used were found in the sheep manure, and 61 per cent of the nitrogen, 56 per cent of the phosphoric acid, and 67 per cent of the potash in the feed and bedding given the cows and horses were found in the mixed manure."

It is estimated that the sheep and swine manure was worth about \$6 and the mixed manure about \$3 per cord at the manure pit.

The effect of phosphoric acid upon the decomposition of sugar in the soil, S. Herke (Kisérlet. Közlem., 18 (1915), No. 5-6, pp. 857-886; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 5, pp. 645, 646; Jour. Soc. Chem. Indus., 35 (1916), No. 21, p. 1125; Chem. Abs., 11 (1917), No. 10, p. 1511).—Experiments are reported which showed that the decomposition of sugar in a soil, as indicated by the liberation of carbon dioxid, is influenced by the chemical composition of the soil and by the presence of certain nutritive salts. In a soil to which phosphoric acid was added the sugar decomposed more quickly than in the same soil without the addition of phosphoric acid. The difference between the amounts of carbon dioxid liberated from the treated and untreated soils increased for a certain time and then decreased.

A certain correlation was observed between the effect of the phosphoric acid on the decomposition of the sugar and the increased yield produced by it in fertilizer experiments. Thus, in a soil where the addition of 0.06 gm. of phosphoric acid per kilogram of soil increased the yield of oats and mustard, the same amount of phosphoric acid increased the amount of carbon dioxid liberated in the presence of 2 per cent of dextrose or saccharose. Increasing amounts of phosphoric acid also gradually increased the liberation of the carbon dioxid liberated.

The presence of calcium carbonate and of ammonium sulphate at the rate of 0.05 gm, of nitrogen per kilogram of soil promoted the decomposition of sugar. Small amounts of nitric nitrogen (0.05 gm, of nitrogen, in the form of sodium nitrate, per kilogram) also increased the liberation of carbon dioxid except in a nutritive solution in which 0.1 per cent sodium nitrate exercised an inhibiting effect. Potassium sulphate increased the liberation of carbon dioxid in some soils and decreased it in others.

These results are taken to indicate that the effect of phosphoric acid is differently influenced by the addition of nitrogenous and potassic compounds according to the nature of the soil, any quantitative variation in one as a rule modifying the action of the other.

The potash question and general farm crops, A. W. Blair (New Jersey Stas. Circ. 67 (1917), pp. 3-7).—It is stated in this circular that with the exception of the very sandy sections of the State, New Jersey soils contain a fair supply of potash which has been derived from the original rocks and glaciated materials. The greater part of this potash is unavailable and, on the basis of work at the station, the incorporation of organic matter, deep plowing, thorough cultivation, and liming are recommended for setting some of it free.

Potash in New Zealand and other countries, P. G. Morgan (Jour. Agr. [New Zeal.], 14 (1917), No. 4, pp. 257-273).—This article gives general information concerning the present potash situation, possible sources of potash, and methods for rendering potash available to the farmer, with special reference to New Zealand conditions. Some of the natural sources of potash recommended for use by farmers in New Zealand are calcareous clay stones, glauconitic rocks, and calcareous green sandstone.

A discussion concerning the rational use of lime on the farm (Bul. N. C. Dept. Agr., 38 (1917), No. 1, pp. 22).—This circular gives information on the selection, purchase, and use of lime for agricultural purposes.

Notes on humus, humogen, and its accessory plant food substances, A. STEAD (So. African Jour. Sci., 13 (1917), No. 6, pp. 239-250).—This is a review of the work of others on the soil humus question, special attention being given to the Bottomley bacterized peat process.

The plant food materials in the leaves of forest trees, P. Serex, Jr. (Jour. Amer. Chem. Soc., 39 (1917), No. 6, pp. 1286-1296).—Experiments conducted to determine the plant food constituents of the leaves of the chestnut, sugar maple, and white oak at the beginning of their activity in spring and at the end of their growth in the fall are reported.

It was found that "the leaves collected in the spring show a higher content of nitrogen and potash than those collected in the fall from the same trees, The phosphoric acid content varies with the species of tree and also with the section of the tree from which the leaves were obtained. The lowest amount of nitrogen and phosphoric acid occurred in those leaves collected from trees grown upon a clay soil. The highest content of nitrogen, phosphoric acid, and potash occurred in those leaves collected from trees grown upon the Holyoke stony loam and Wethersfield loam. The leaves from the upper branches of the maple and oak have a higher content of nitrogen, phosphoric acid, and potash in the majority of cases than those taken from the lower branches. case of the chestnut the reverse appears to be true, the leaves from the lower branches having the larger amount of nitrogen, phosphoric acid, and potash, with some exceptions, than those removed from the upper branches. The estimated theoretical cash value of a ton of leaves calculated upon a 20 per cent moisture basis varies from \$3 to \$6.50, depending upon the kind of leaves and upon what portion of the tree they were grown. The cost of collecting and handling would probably be greater than the value of the leaves, thus

making it inadvisable in most cases for farmers to spend their time in this way."

Fertilizers and industrial wastes, F. W. Brown (Saturday Even. Post, 189 (1917), No. 48, pp. 121, 122; Amer. Fert., 47 (1917), No. 1, pp. 58, 62, 64, 68).—Attention is called to the loss of nitrogen, potassium, and phosphoric acid compounds in industrial wastes, especially of potash in cement mills and blast-furnace gases.

Analyses of fertilizers (Bul. N. C. Dept. Agr., Sup., 38 (1917), No. 2, pp. 4).— This bulletin contains the results of actual and guaranteed analysis of 54 samples of fertilizers and fertilizing materials collected for inspection in North Carolina in February, 1917.

Fertilizer analyses (Bul. N. C. Dept. Agr., 38 (1917), No. 3, pp. 14).—This bulletin contains the results of actual and guaranteed analyses of 268 samples of fertilizers and fertilizing materials collected for inspection in North Carolina during the spring of 1917.

# AGRICULTURAL BOTANY.

International catalogue of scientific literature. M—Botany (Internat. Cat. Sci. Lit., 13 (1916), pp. VIII+812).—This volume (E. S. R., 35, p. 29), though listing mainly the literature of 1913, includes some of previous years, going back as far as 1901.

[Some investigations in the department of experimental evolution] (Carnegie Inst. Washington Year Book, 15 (1916), pp. 133, 134).—This section of the report of this department includes condensed information on the results of work by J. A. Harris on the correlation between characters of leaves in normal and abnormal bean seedlings, the correlation between homologous parts of a plant, and a table of osmotic pressures based on depression of freezing point; by him with Lawrence on plant sap in relation to environment on the Arizona deserts; and by these with Gortner on expressed vegetable saps as affected in their concentration by continued pressure.

Wild flowers worth knowing, N. Blanchan, adapted by A. D. Dickinson (Garden City, N. Y.: Doubleday, Page & Co., 1917, pp. XVIII+270, pls. 48, figs. 39).—This book, adapted from Nature's Garden, a previous work by the author, deals with a number of well-known families of plants. The nomenclature and classification of Gray's New Manual of Botany, seventh edition, are followed throughout.

Fungi from Val d'Aosta, P. A. SACCARDO (Nuovo Giov. Bol. Ital., n. ser., 24 (1917), No. 1, pp. 31-43).—Among a number of fungi collected at various altitudes in Val d'Aosta in 1916 and submitted for examination to the author, he has designated as new species Clitocybe thuilensis, Exobasidium æquale, Sphæronema oreophilum, Næmosphæra chanousiana, Rhabdospora bernardiana, Oylindrosporium vaccarianum, Sporodesmium fumagineum, and Nothodiscus antoniæ, the last named being considered also as representing a new genus.

Fungi causing discolorations in paper, P. Sér (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 5, pp. 230-232).—Brief descriptions are given of discolorations caused in paper by the development of spores of certain fungi, also an account of culture studies therewith.

On Stigeosporium marattiacearum and the mycorrhiza of the Marattiaceæ, C. West (Ann. Bot. [London], 31 (1917), No. 121, pp. 77-99, pl. 1, figs. 9).—
The author describes a fungus, supposedly a new species and here named S. marattiacearum, which forms an endotrophic mycorrhiza with roots of certain genera (Angiopteris, Archangiopteris, Kaulfussia, and Marattia) of Marattiaceæ, giving a discussion of its biology, systematic position, and probable

life history. A brief description is also given of a mycorrhizal fungus said to enter into association with roots of Dancea.

The chemical conditions for the development of reproductive organs in yeasts, K. Sarro (Jour. Col. Sci. Imp. Univ. Tokyo, 39 (1916), Art. 3, pp. 73).—
The author has made a study of the influences bearing upon the production of the organs of reproduction in Zygosaccharomyces mandshuricus, Schizosaccharomyces octosporus, and Saccharomyces mandshuricus. He states that though these resemble other fungi in that reproduction stands in close relation to the quantity and quality of the chemical substances available, reproduction depends also, in case of certain organisms, upon the presence of specific chemical substances. Several such requirements are indicated. Among the significant physical considerations, osmotic activity plays an important rôle in determining concentrations and consequent development of reproductive parts. The factors, both internal and external, are thought to be very numerous, and together to constitute a very complex mechanism.

Microchemical studies in the progressive development of the wheat plant, Sophia H. Eckebson (Washington Sta. Bul. 139 (1917), pp. 3-21, figs. 13).— The author states that the progressive chemical changes during the development of the wheat grain are correlated with morphological changes, each definite period of the morphological development being characterized by some chemical difference. The progression of these chemical changes was found to be alike in all varieties tested of both winter and spring wheat.

Summarizing her results, the details of which are given, the author reports that inorganic materials are high in the young plant. The largest amount of potassium nitrate was found, chiefly in the root and stem, just before the formation of the spike, after which it decreased gradually. Free magnesium quickly fell to a minimum during the formation of the aleurone, while free phosphate rose to a maximum during development of the sporogenous tissue, falling to a minimum after the development of the sex cells.

Asparagin is thought to be a very important nutritive substance, and it was found together with fructose in all young growing parts. The occurrence of pectic substances on the stigma is considered especially important in reducing the rate of water absorption by pollen grains. During the period from the fertilization of the egg to the mature grain, there is said to be a stream of nutrient materials for the growing embryo coming to the endosperm from the leaves and glumes. Any excess of sugar was found to condense immediately into starch. Excess of asparagin and amino acids remained as such in the endosperm cells until desiccation of the grain. The nitrogenous compounds in the endosperm just before ripening of the grain, aside from aleurone and protoplasm, are asparagin, arginin, histidin, and some leucin. No glutamin was found.

Protein, which has the physical characteristics of gluten, is said to appear in the storage cells on desiccation of the grain, the amino acids and most of the asparagin disappearing. The formation of the storage protein in wheat is believed to be a condensation process.

The physiological rôle of calcium in vegetable life, Thérèse Robert (Rev. Gén. Sci., 28 (1917), No. 4, pp. 101-108).—The author discusses the ability of plants to utilize calcium in their economy, as deduced from the examination of a very large number of investigations by various authors, taking up more particularly the relation of calcium to phanerogams, including the distribution of calcium in its various forms in the plant body; its necessity, or at least utility, in relation thereto; its mode of action or rôle as plastic, catalytic, toxic, or antitoxic; and its replacement or substitution by other elements.

The influence of some organic substances on plants, I, G. CIAMICIAN and C. RAVENNA (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 26 (1917), I, No. 1, pp. 3-7).—This article, which is related to previous work (E. S. R., 36, pp. 329, 432) and is regarded as suggestive of further studies on a larger scale, discusses briefly the effects on plant growth of several organic substances, including mandelic nitrile, nicotin, strychuin, caffein, and morphin.

Quantitative experiments demonstrating the mechanism of the inhibition of growth, J. Loeb (Proc. Soc. Expt. Biol. and Med., 14 (1917), No. 7, pp. 131, 132).—The author has studied by a quantitative method the laws of inhibition, several reports regarding which have been noted previously (E. S. R., 34, p. 730; 35, p. 820; 37, pp. 324, 325). Proceeding upon the hypothesis of inhibition of growth by one organ in relation to another by the removal of material necessary for growth, and upon the expectation that if such were the case the total mass of shoots produced by a leaf in a certain time would be approximately the same regardless of their number, he claims to have found that this is true to a surprising degree of exactness. The quantitative data so obtained, as briefly indicated in the statement, are relied upon to furnish the basis of a chemical theory of regeneration.

Studies in permeability.—IV, The action of various organic substances on the permeability of the plant cell, and its bearing on Czapek's theory of the plasma membrane, W. Stiles and I. Jörgensen (Ann. Bot. [London], 31 (1917), No. 121, pp. 47-76, figs. 15).—The authors have carried forward the series of studies the last noted of which was contributed by Mildred Hind (E. S. R., 36, p. 433). The present contribution relates partly to tests made by the author as bearing upon Czapek's theory of a plasma membrane, earlier (E. S. R., 24, p. 137) and later reports on which are discussed, with a statement of alleged reasons for the rejection of some views held by that author.

The method employed is here described in more detail than in the article previously noted (E. S. R., 35, p. 224), with an account of its supposed advantages over the methods formerly used, such as greater exactness and more general applicability.

It is stated that with each organic substance a higher rate of exosmosis corresponded to a higher concentration of the substance employed. Equimolecular solutions of different substances do not bring about the same exosmosis. The rate of exosmosis produced by a solution is not a function of its surface tension alone. A concentration below which exosmosis of electrolytes could not take place was not found. In the attempt to deduce a mathematical time-rate expression for exosmosis, it was found that the equation expressing the results of actual experiments exactly resembled that expressing theoretical considerations.

The osmotic concentration of the sap of the leaves of mangrove trees, J. A. HARRIS and J. V. LAWRENCE (Biol. Bul. Mar. Biol. Lab. Woods Hole, 32 (1917), No. 3, pp. 202-211).—Presenting the results of a series of determinations of the leaf tissue fluids of Avicennia nitida, Rhizophora mangle, and Laguncularia racemosa on the southern shore of Jamaica and in southern Florida, the authors state that the concentration of these fluids is relatively high throughout, the range as noted lying between the limits of 20 and 50 atmospheres. Avicennia apparently developed a much higher concentration than the other species in the same environment.

The origin of chromoplasts and the mode of formation of xanthophyll and carotin pigments, A. Guillermond (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 5, pp. 232-235).—Giving a résumé of related studies to date, the author states that the various forms in which pigments may appear can be arranged under three general heads. These are according as to whether the

pigment in question occurs in a diffused or finely granulated state in the mitochondria or the chloroplasts derived from them, as a result of a process of crystallization subsequent to such origin, or in diffused granular or crystalline form in the large chromoplasts resulting from the metamorphosis of the chloroplasts previously formed out of the mitochondria, such mitochondrial origin explaining the elongated early form of the chloroplasts. The formation of vegetable pigments is effected by a process very similar to that which has been recently shown to occur in the cells of animals.

The anthocyanin pigments of plants, Muriel Wheldle (Cambridge: University Press, 1916, pp. X+318).—The object of this book is to provide a somewhat complete account of the various reports which have been made regarding the anthocyanin pigments as studied along botanical, chemical, and genetical lines. While not claiming that anthocyanins will ever possess great botanical significance, when compared with that of chlorophyll, for example, the author thinks they may develop a wide field for research in connection with problems of inheritance. Owing to the increasing availability of satisfactory methods for the isolation, analysis, and determination of the constitutional formulæ of these pigments on the one hand and Mendelian methods for determining inheritance on the other, the two methods combined furnish a reasonable hope that inheritance phenomena may eventually be expressed in terms of chemical composition and structure.

The eight chapters of the first part deal with the anthocyanins as regards their morphological and histological distribution, their properties and reactions, isolation and constitution, physiological conditions, factors, reactions, and significance. The second part considers the anthocyanins in relation to genetics.

An extensive bibliography is given.

Environmental influences on nectar secretion, L. A. Kenoyer (Iowa Sta. Research Bul. 37 (1916), pp. 219-232, fig. 1).—The results are given of studies of a number of species of flowers, among them varieties of clovers, alfalfas, dandelions, and lilies, to determine the factors which stimulate or retard the secretion of nectar.

It was found that by increasing humidity, the secretion by the nectaries of water, but not of sugar, was increased. Excessive water supply lessens the sugar surplus, and dilution and washing by rain causes much of the sugar of the nectaries to be lost. The rate of secretion for both sugar and water increases with the temperature up to a certain optimum. Accumulation of sugar in the flower varies inversely as the temperature. The optimum condition for sugar secretion was found to be an alternation of low and high temperatures. Variation of atmospheric pressure has no marked influence on secretion. Sugar excretion is markedly diminished in darkness on account of the limitation of the food reserves of the plant. Water excretion may or may not be limited in this manner, depending on the species. The greatest amount of sugar was found to be secreted under the most favorable conditions for growth and vigor for the plant. Other things being equal, nectar is most abundant early in the blooming season, and the accumulation and secretion of sugar is most pronounced near the time of the opening of the flower.

Environmental influences on nectar secretion, L. A. Kenoyer (Bot. Gaz., 63 (1917), No. 4, pp. 249-265, flg. 1).—This is essentially the same as the article noted above.

The consequences of precocity in spring vegetation, 1916, O. Opola (Compt. Rend. Acad. Agr. France, 3 (1917), No. 1, pp. 49-52).—Warm weather during nearly all of the winter and spring of 1915-16 resulted in the production of three periods of blooming in apricot trees, occurring about the middle of the months of January, March, and April. A heavy snow February 25 and con-

tinued cold completely arrested growth for the time being, and resulted in a very great reduction of the fruit crop.

Fruit injury during the fumigation of citrus trees, R. S. Woglum (Fruit World Austral., 17 (1916), No. 3, pp. 70-72).—Giving the results of observations on the degrees and phases of fruit pitting after the use of cyanid gas to kill insects on citrus trees, the author holds that the cyanid gas itself is the basic cause of general fruit pitting, other factors being the strength of the gas used, length of exposure, condition of plants treated, and moisture, along with minor or contributing factors.

Mechanical injury, favoring the gas injury, is caused by drawing the tents over the trees, especially when they are wet or when the tent poles are low. Pressures on the growing fruit appear to weaken resistance near such points, as in cases where fruits are pressed together. Trees which have been sprayed with Bordeaux mixture should not be fumigated for about a year after spraying, as leaves and fruit may be dropped as a result of such treatment.

The history and legal phases of the smoke problem, L. Johnson (Metallurg. and Chem. Engin., 16 (1917), No. 4, pp. 199-204).—Dealing very briefly with the history and bearings of smoke-injury problems, the author reviews some phases of the investigation carried out by, or in connection with, the Selby Smelter Commission selected to investigate the questions arising in the Selby smelter smoke zone (E. S. R., 34, p. 716; 35, pp. 133, 243, 244).

It is said to have been found that dust and acid vapors were practically negligible factors in the fume problem so far as vegetation is concerned, any damage actually done being traceable almost wholly to sulphur dioxid. Vegetation can stand on the average, it is said, 50 times the strength of sulphuric acid that it can bear of sulphur in the form of sulphur dioxid, the latter, however, producing little or no injury when the plants are not in leaf. Both crude sulphur and sulphuric acid increased crop yields in most instances, and practically without exception in alkaline soils. When leaf stomata were closed, as in darkness, the plants were very resistant to sulphur dioxid.

Four prominent factors in this connection were light, humidity, temperature, and direction of the wind (where the latter is constant, puffs of wind having but little influence in this connection). Much of the injury previously ascribed to smoke is said to have been due to such factors as fungus diseases.

#### FIELD CROPS.

The experimental error in field trials and the effect on this error of various methods of sampling, C. Miyake (Ber. Öhara Inst. Landw. Forsch., 1 (1916), No. 1, pp. 111-121, figs. 2).—The experimental error of field tests with barley and rice on single unit plats, successive unit plats, and scattered unit plats is discussed, and data giving the standard deviation on the plats and the estimated standard deviation are presented in tabular form. The conclusions reached from these data are that the standard deviation decreases with the size of the plat, that it is smaller with the scattered unit plats than with the successive unit plats, and that the scattered unit plat method is superior to the successive unit plat method in point of sampling.

The author found the probable error on a  $\frac{1}{10}$ -acre plat of barley to be about  $\pm 3.3$  per cent, and of rice about  $\pm 1.8$  per cent. He concludes that the probable error in plats of this size is about  $\pm 2$  per cent as contrasted with the results obtained by Hall and Wood (B. S. R., 26, p. 732), from which they calculated the probable error in field experiments to be approximately  $\pm 5$  per cent. He attributes this difference to the more intensive cultural methods employed in Japan.

Five methods for sampling a rice crop in the field to estimate the total yield are described and were tested, and the results presented in tabular form. In order to place the results on some basis for comparison, the estimated standard error has been calculated in each case according to the following formula:

$$\omega = \sigma \sqrt{\frac{n}{300}}$$

when n is the total number of plants sampled,  $\sigma$  the real standard error, and 300 a constant. From these results the author concludes that either the "diagonal" or "scattered" method of sampling is superior to the other methods tested.

[Report of field crop work], J. M. Scott (Florida Sta. Rpt. 1916, pp. 23-29).—Fertilizer tests with Japanese cane, velvet beans, and sweet potatoes, variety tests with cowpeas and velvet beans, and field tests with cotton and sorghum are briefly noted.

The 1915 yield of Japanese cane showed a decrease, as compared with that of 1914, of more than 50 per cent on some plats, while on others the decrease varied from 10 to 20 per cent. In the spring of 1915 land grown continuously with Japanese cane under varying fertilizer treatments since 1908 was plowed and replanted to cane, using the same fertilizers. The results are interpreted as strongly indicating the advisability of replanting Japanese cane every three or four years. The highest yield, 31.9 tons of green forage per acre, was secured from the plats receiving 84 lbs. of muriate of potash and 224 lbs. of acid phosphate. The lowest yield, 18 tons per acre, was obtained from the plat receiving 112 lbs. of dried blood and 224 lbs. of acid phosphate. Applications of ground limestone failed to show any substantial benefit after the first application in 1909.

Fertilizer tests with velvet beans gave the highest average yield, 658.4 lbs. of pods per acre, with an application of 360 lbs. of Thomas slag, while the lowest yield, 583.9 lbs., was secured from a 400-lb. application of acid phosphate. The untreated checks yielded 616 and 642.8 lbs. per acre, respectively.

An application of 112 lbs. of dried blood, 224 lbs. of acid phosphate, 84 lbs. of sulphate of potash, and 2,000 lbs. of ground limestone showed the highest average yield of sweet potatoes, estimated at 269.6 bu. per acre. The lowest yield, estimated at 99.6 bu., was obtained from a plat receiving 112 lbs. of dried blood and 224 lbs. of acid phosphate.

Of the four varieties of cowpeas tested for forage production, Monette S. P. I. No. 1541 was highest with a yield of 1,705.1 lbs. per acre and Brabham second with a yield of 1,577.9 lbs. In seed production Monette S. P. I. No. 1541 yielded 531.7, Brabham 517.3, and S. P. I. No. 27863 258.2 lbs. of seed pods per acre.

Tests with velvet beans included the Yokohama, Osceola, Florida, Chinese, and Wakulla varieties, which yielded 1,893, 1,394.6, 1,320, 1,229.5, and 856 lbs. of pods per acre, respectively.

The average acre yield of seed cotton amounted to 349.5 lbs. per acre. Selection work with cotton is being continued.

The seed heads of Sumac sorghum grown on the station farm amounted to 1,236.25 lbs. per acre green weight and 1,129 lbs. dry weight. The average yields in green and dry forage amounted to 9,512 and 3,037 lbs. per acre, respectively, based on a 2-acre yield.

[Experiments with field crops in Maine], C. D. Woods (Maine Sta. Bul. 260 (1917), pp. 102-120).—Variety and rate-of-seeding tests with oats were continued as previously noted (E. S. R., 35, p. 33), and fertilizer experiments with oats and potatoes reported.

Sixteen varieties of oats were tested at Aroostook farm in 1916, giving an average yield of 61.4 bu. of grain and 3,412 lbs. of straw per acre. Maine 340 was highest, with a yield of 75.6 bu. It also matured from three to six days earlier than Early Pearl and Siberian, which yielded 66.6 and 66 bu. per acre, respectively. The early varieties Kherson and Daubeney, maturing from a week to ten days earlier than the other varieties, yielded only 61.3 and 57.2 bu., respectively.

Eight commercial varieties of oats and ten pure-line selections were tested during 1916 at Highmoor farm. The season is reported as having been very unfavorable for the oat crop. Early Pearl, with a yield of 56.7 bu., was the leading commercial variety tested, while Maine 340, with a yield of 52.7 bu. per acre, was first of the pure-line selections.

In the rate-of-seeding tests with oats the 14-pk. rate again gave the highest yield, 71.3 bu. per acre. The 16- and 20-pk. rates yielded 70.2 and 69.5 bu., respectively, but showed a distinct tendency to lodge.

Fertilizer experiments with oats on the Aroostook farm included a series of plats receiving an application of 500 lbs. of commercial fertilizers each per acre, having 4 per cent nitrogen, 8 per cent available phosphoric acid, and from 0 to 8 per cent potash. Oats were also grown on land seeded to potatoes in 1915 with and without potash. The results indicate that potash is not a limiting factor in oat production in these soils, and that the application of potash the previous year does not affect the oat crop following.

Experiments on the effect of omitting potash fertilization upon the potato crop were continued, with more pronounced effects in favor of potash fertilization than previously observed (E. S. R., 35, p. 34). The average yield for the two years from the plats receiving no potash was estimated to be 111 barrels, and from those plats receiving 8 per cent potash 134 barrels. It is concluded that as little as 45 lbs. of potash per acre will give a profitable increase in the yield of potatoes, at least when grown on sod land, while a profitable yield can be obtained without the use of potash for at least one year.

The comparison of sulphate of ammonia with nitrate of soda as a source of nitrogen for potato fertilization was continued. From the results of three years of experimental work it is concluded that at least two-thirds of the total nitrogen can be supplied in the form of sulphate of ammonia without decreasing the yield. These experiments are to be continued in order to determine the effect of these different substances under different seasonal conditions.

In comparing methods of application of fertilizers to the potato crop it has been concluded that fully as good, if not better, results can be obtained by applying all the fertilizer in the planter. It appeared that up to 1,500 lbs. per acre nothing was gained either by broadcasting before planting or by applying a part at the first cultivation.

Field tests are briefly noted on the use of common salt in fertilizing onts. potatoes, grass, and turnips to liberate the unavailable potash in the soil. Increased yields of turnips were noted, but no benefit was found with the other crops. No appreciable effect of the salt on the soil potash was observed.

Results of breeding experiments, C. B. WILLIAMS (North Carolina Sta. Rpt. 1916, pp. 16-18).—Selection and variety tests with cotton, corn, soy beans, and velvet beans are briefly reported.

Cotton Selection No. 29 is deemed the best yielder thus far secured, producing 252 lbs. of seed cotton per acre more in 1915 than the unselected seed and leading in the variety tests at the station farm by 94 lbs. of seed cotton per acre. A uniform strain of cotton was secured at Aberdeen in 1915, which gave a staple  $1\frac{\pi}{12}$  in, in length and compared favorably in yield with the local short-

staple cottons. A strain introduced into Edgecombe County in 1915 produced 158 lbs. of lint per acre more than the prevailing local variety.

Cooperative ear-to-row corn tests resulted in yields estimated to range between 23.1 and 58.7 bu. of shelled corn per acre from selections made the previous fall. The 10 best selections averaged 54.2 bu. while the average yield of all selected seed was 42 bu. per acre.

Mammoth Yellow and Tokyo soy beans are recommended for seed production for the eastern and lower Piedmont sections of the State, while Haberlandt and Wilson are recommended for the upper Piedmont and mountains. Virginia is deemed superior to all varieties tested for hay production in all sections of the State.

Velvet beans have not proved successful in the western portion of the State, while from Wake County eastward the varieties are classed as follows: For hay production, Florida Velvet, One Hundred Day Speckle, Chinese, Wakula, and Yokohama; and for seed production, One Hundred Day Speckle, Wakula, Yokohama, Chinese, and Florida Velvet. One Hundred Day Speckle is deemed best for North Carolina conditions generally.

Daily variation of water and dry matter in the leaves of corn and the sorghums, E. C. Miller et al. (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 1, pp. 11-46, pl. 1, figs. 10).—In connection with studies previously noted (E. S. R., 35, pp. 437, 529), the author has determined the daily variation of the water and dry matter content of the leaves of Pride of Saline corn, Dwarf milo maize, and Blackhull Kafir corn. A knowledge of the variations of the amount of water in the leaves was expected to throw light on the relative ability of these plants to absorb water from the soil and transport it to regions of loss through transpiration, while a study of the variations of dry matter in the leaves was expected to show the relative power of the plants to manufacture food under different climatic conditions. The experiments were conducted during the summers of 1914, 1915, and 1916 at the Garden City substation of the Kansas Experiment Station.

Soil samples for moisture determinations were taken for each foot to a depth of 6 ft. either a few days before or after the experimental work with the leaves. The results of the determinations, together with the wilting coefficient and moisture equivalent for each of the several plats, are reported in tabular form.

Livingston's porous-cup atmometers with a coefficient of 74 were employed to determine hourly evaporation. The atmometers were placed 2 ft. from the ground, connected with burettes so that readings could be made to 0.1 cc., and evaporation in cubic centimeters reported in tabular form for the different periods of leaf sampling for each year of the experiment.

Leaf samples, each with an area of 1 sq. cm., were taken every two hours during an experiment from 30 representative plants of each variety. One leaf was chosen on each plant to furnish all the samples desired for a given experiment. The samples were taken by means of a Ganong leaf punch.

Nine experiments were conducted in 1914, two in 1915, and four in 1916. Four of the 1914 experiments extended through the daylight hours only, all others ranging from 24 to 40 hours in length. The amount of water and dry matter for each square meter of leaf were determined every two hours for a total of 22 days and 10 nights, and the percentage of water calculated on both a wet and dry basis. The data obtained are presented in tabular form, expressed graphically, and the results discussed in some detail.

The following summarized statement shows the variation of the water content of the leaves of the plants studied during the three years 1914-1916:

Variation of the water content of the leaves of corn, Kafir corn, and mile maize, 1914-1916, at Garden City, Kans.

Time of day.	Kind of plant.	Loss.			Gain.			Net gain (+) or loss (-).	
		Num- ber of cases.	Average loss of leaf water per square meter of leaf. The average rate of increase of dry matter for each square meter of leaf for corn, Kafir corn, and mile maize during each two-hour period of the day has been estimated as follows:

Average rate of increase of dry matter per square meter of leaf.

Kind of plant.	7-9 a. m.	9-11 a. m.	11 a.m 1 p. m.	1–3 p. m.	3–5 p. m.
	Gm.	Gm.	Gm.	Gm.	Gm.
Corn	2.2	1.1	0.8	0.7	0.8
Kanr com	1.7	1.2	.7	1.2	.7
Milo maize	1.3	1.5	2.2	2.0	. 1

The author summarizes his observations and conclusions as follows:

The amount of water in the leaves of milo maize was found to be lower at all times of the day and night than that of corn or Kafir corn leaves at a similar stage of development, while the average water content of these two was practically the same. The water content of the leaves of corn, Kafir corn, and milo maize averaged 118.5, 120, and 107 gm., respectively, for each square meter of leaf during the day (7 a. m. to 7 p. m., inclusive) and 127.9, 132.7, and 115.5 gm., respectively, for the night periods (7 p. m. to 7 a. m., inclusive). The average variation between the maximum and minimum water contents of the leaves from 7 a. m. to 7 p. m. was 13.8, 8.4, and 7.8 gm. for each square meter of leaf of corn, Kafir corn, and milo maize, respectively, and the average range between the maximum water content of the leaves during the night and the minimum amount during the day, 23.8, 25.9, and 21.7 gm., respectively.

Evaporation during the 22 days reached a maximum 18 times between 2 and 3 p. m. and 4 times between 3 and 5 p. m. Two-thirds of the observations for corn and mile maize and nine-tenths of those for Kafir corn showed a minimum water content of the leaves from two to four hours before maximum evapora-

tion was reached, while in the remaining tests the minimum amount of leaf water occurred at the time of maximum evaporation.

On a wet basis the maximum and minimum percentages of water in the leaves showed an average variation during the day of 3.5 for corn, 3.2 for Kafir corn, and 4.5 for milo maize. The average variation between the minimum percentage of water during the day and the maximum during the night was 5.4, 5.9, and 6, respectively. On a dry basis the average difference between the minimum and maximum percentages of water during the day was 39.5 for corn, 31.1 for Kafir corn, and 35.9 for milo maize. The average range between maximum and minimum water content during the night was 37.5, 47.5, and 40 per cent, respectively, while the average range between the minimum percentage of water during the day and the maximum percentage during the night was 67.8, 67.2, and 51.2, respectively.

The average dry weight of a square meter of leaf for all observations was 48.2 gm. for corn, 52.5 for Kafir corn, and 56.2 for milo maize. The average difference between the minimum and maximum amounts of dry matter in the leaves for each square meter during the day was 4, 4.8, and 8 gm. for corn, Kafir corn, and milo maize, respectively. The increase in dry matter began at daybreak and usually reached a maximum between 2 and 5 p. m., the rate of increase during that portion of the day when the climatic conditions were severe being higher for milo maize than for either corn or Kafir corn.

The results are held to indicate that the sorghums, more particularly milo maize, can absorb water from the soil and transport it to leaves more rapidly in proportion to the loss of water from the plant than can corn. As a result of this the sorghums are enabled to produce more dry matter per unit of leaf area under severe climatic conditions than can the corn plant.

Experiments with legume crops under irrigation, J. S. Welch (*Idaho Sta. Bul. 94* (1917), pp. 14, figs. 5).—Field tests and observations with various legumes under irrigation at the Gooding substation in southern Idaho are noted and briefly discussed.

Rate-of-seeding tests with alfalfa during the period of 1910-1912, inclusive, gave average yields of 4.021, 3.726, 4.364, 3.855, and 3.702 tons per acre, with 20-, 16-, 12-, 8-, and 4-lb. rates, respectively.

A comparison of the corrugation method with the flooding method for irrigating alfalfa showed the former to be far superior for the first season of growth, after which it failed to show any advantage over the latter method. A comparison of different sized streams for the application of irrigation water during 1915–16 gave average yields of cured hay of 4.246, 2.842, and 2.291 tons per acre for streams of 0.3, 0.65, and 1.2 cu. ft. per second, respectively. Tests on the duty of water for alfalfa hay during 1911–1914, inclusive, indicated that for three crops of hay an application of about 2.75 acre-feet per acre gave best results.

For alfalfa-seed production light, frequent applications of water sufficient to maintain a uniform but not excessive soil moisture content were deemed best.

Field tests with red clover indicate that the common is the most important strain, and that grown for hay it requires practically the same treatment as alfalfa. The heaviest yields of seed were obtained from plats clipped late in May. Increased yields of barley, wheat, and oats estimated at 17.57, 10.74, and 9.47 bu. per acre, respectively, were attributed to the plowing under of a red clover crop as a green manure.

Alsike and white clovers are deemed valuable as pasture mixtures, while crimson clover has not proved to be sufficiently hardy for Idaho conditions.

In variety tests with field peas the Amraoti was first, with an average yield of 39.01 bu. per acre for 1912-1915, inclusive. Other varieties have given satisfactory yields. Field peas sown in rows 21 in. apart and cultivated gave an average yield of 32.49 bu. per acre as compared with an average of 38.98 bu. for peas drilled in. The best results with field peas were secured with one irrigation just before blooming, followed by a second application when the peas were forming.

In rate-of-seeding tests with different mixtures of field peas and oats the highest average yield, 3.223 tons of cured hay per acre, was secured from a rate of 70 lbs. of peas and 50 lbs. of oats. An estimated net return of \$39.68 per acre was secured from "hogging off" field peas alone in 1916, while a mixture of three-fourths field peas and one-fourth wheat sown at the rate of 90 lbs. per acre was estimated to give a net return of \$45.20.

Vicia villosa, the White Navy field bean, and the horse bean have proved valuable as forage crops. Soy beans and cowpeas have not proved hardy.

The management of irrigated grass pastures, J. S. Welch (*Idaho Sta. Bul.* 95 (1917), pp. 17, figs. 4).—Results at the Gooding substation previously noted (E. S. R., 32, p. 628) are reviewed, together with additional data secured from grazing tests and observations during 1915-16. Certain important phases of pasture management under irrigation conditions are emphasized.

Experiments with small grains under irrigation, J. S. Welch (Idaho Sta. Bul. 93 (1917), pp. 24, figs. 5).—The results of variety and irrigation experiments with spring and winter wheat and barley and spring oats at the Gooding substation, conducted in cooperation with the Irrigation Investigations of the U. S. Department of Agriculture, are reported for the period of 1909–1916, inclusive.

The soft, white, spring wheats are considered best adapted for growth under irrigation. The Dicklow, with a 6-year average yield of 46.1 bu. per acre, was deemed the best spring wheat variety, and Jones Fife and Turkey Red, with 2-year average yields of 53.6 and 52.4 bu., respectively, the best winter varieties. Although drought-resistant, the durum wheats are not recommended for average irrigation conditions.

The irrigation experiments with spring wheat indicated that the highest yields were secured from one irrigation in each of three successive stages of growth and amounted to an average of 43.9 bu. per acre for the period of 1911-1916, inclusive. One irrigation in the first and second stages each gave an average yield of 43.5 bu., and one irrigation in the first stage only, an average of 33.6 bu. per acre. When irrigation was withheld until the third stage the average yield was 22.7 bu., and it was considered as of no value to the crop. It is recommended that if but one irrigation can be made it be applied just before the first jointing stage of growth.

Duty-of-water experiments with spring wheat from 1910-1916, inclusive, indicated that a total application of not more than 1.25 acre-feet of water per acre gave the best results. For winter wheat production one irrigation of slightly less than 0.75 acre-foot of water per acre applied just before heading was deemed sufficient from results secured in tests conducted in the years 1910, 1911, and 1912.

In variety tests with spring barleys Trebi, with 95.5 bu., Beldi No. 1209, with 87.8 bu., and Sandrel, with 82.9 bu. per acre gave the highest yields for the 6-rowed types; Bohemian, with 84.21 bu., and Horn, with 81.65 bu. for the 2-rowed types; and Eureka, with 63.4 bu. for the hull-less type.

In irrigation tests with spring barley a study was made of the influence of different sized streams, employing 1.2, 0.65, and 0.3 cu. ft. per second. The tests were conducted during 1915-16, and the average yields were 54.7, 55.9,

and 49.2 bu. per acre, respectively. Duty-of-water experiments with spring barley extending over the period of 1910-1914, inclusive, indicated the use of approximately 1.5 acre-feet of water per acre as sufficient.

The Utah and Tennessee winter barleys yielded 69.7 and 60.8 bu. per acre, respectively, for a 2-year average. Duty-of-water experiments with winter barley extending over the 3-year period of 1913-1915 gave the best results with one irrigation of about 0.43 acre-foot of water per acre applied just before heading.

The leading varieties of oats included Swedish Select, Wisconsin Pedigree No. 1, and Silver Mine, with average yields of 96.6, 96.5, and 96 bu. per acre, respectively.

Duty-of-water experiments with oats indicate that the oat crop requires approximately 1.75 acre-feet of water per acre.

Yields of winter grains in Illinois, W. L. Buelison and O. M. Allyn (Illinois Sta. Bul. 201 (1917), pp. 96-110, figs. 3).—Field tests with winter varieties of wheat, rye, and barley conducted at DeKalb (DeKalb Co.), Urbana (Champaign Co.), and Fairfield (Wayne Co.) are reported and briefly discussed. The results of the wheat variety tests conducted at Cutler (Perry Co.) and previously noted (E. S. R., 19, p. 1035) are summarized, and tests with rye, barley, emmer, and oats reported for the winter of 1915-16. The data are presented in tabular form.

The winter wheat variety tests at DeKalb were begun in 1907 and Dawson Golden Chaff employed as a standard of comparison. Turkey Red is deemed the principal high-yielding variety for northern Illinois, while other high-yielding varieties grown for a minimum of three years include Turkey 9–233, Malakoff 5–458, Minnesota Reliable, Wheedling 5–464, Kharkof, and Malakoff, with average yields of 37.2, 36.7, 36.1, 35.2, 32.6, and 31.4 bushels, respectively. Turkey Red has given a 7-year average yield of 35.4 bu. per acre.

Winter barley all winterkilled. Average yields of 55.5 and 47 bu. per acre, respectively, were secured from four tests each of Petkus winter rye and Wisconsin Pedigree rye.

Variety tests with winter wheat at Urbana were begun in 1904, using Turkey Red as a standard variety. The average yields of the leading varieties tested five years or more were as follows: Turkey Red 42.4 (12 years), Malakoff 42, Fultz, 42.1, Hungarian 39.7, Pesterboden 41.8, Beloglina 40.4, Kharkof 42.6, and Dawson Golden Chaff 39.5 bu. per acre. Other promising strains for central Illinois are Turkey Hybrid 509 and Dawson Golden Chaff 9-225.

Tests with winter wheat at Fairfield were begun in 1906, using Fulcaster as a standard variety. The following varieties have given the highest average yields on a percentage basis for a minimum of three years: Fulcaster, Economy, Missouri Pride, Indiana Swamp, Wheedling, Harvest King, Rudy, and Poole, with 15.9 (10 years), 16.9, 15.8, 14.9, 14.5, 14.3, 12.3, and 12 bu. per acre, respectively. Fulcaster was outyielded several years by Economy, Wheedling, Missouri Pride, and Harvest King. The hard wheats such as Turkey Red and Kharkof did not prove to be adapted to southern Illinois conditions.

The following results were secured with winter grain at Cutler in 1916: Wisconsin Pedigree rye 43.4 bu., Wing Black rye 46.8 bu., Salzer winter barley 22.7 bu., Michigan winter barley 17.5 bu., and Winter emmer 52 bu. Winter oats did not prove hardy.

The characteristics of the winter wheat varieties tested at DeKalb, Urbana, and Fairfield are noted in tabular form.

Bean culture, V. C. BRYANT (California Sta. [Pub., 1917], pp. 2).—A brief popular outline of the cultural practices deemed best for bean production in California.

Dried bean production in Illinois, C. E. Dubst (Illinois Sta. Circ. 201 (1917), pp. 8).—A general discussion of the production and harvesting of beans for drying as human food, together with a brief note on insects and diseases.

Field bean production, R. W. DE BAUN (New Jersey Stas. Circ. 70 (1917), pp. 4).—The methods for production of field beans in New Jersey are briefly discussed.

Studies of variation and correlation of weight and sugar content of beets, especially sugar beets, W. Oetken (Landw. Jahrb., 49 (1916), No. 1, pp. 1-103. figs. 4).—The author outlines the object of his investigations and describes the material used and the methods employed in connection with a series of experiments previously noted (E. S. R., 35, p. 640). A number of formulas are presented and explained for determining the mean, the standard of deviation, the coefficient of variation, regression, the correlation coefficient, the excess, etc.

The variability in weight and sugar content was studied in respect to the individual and to a series of individuals. Considerable data are presented in tabular form and discussed in detail.

A list of 75 articles comprising the literature cited is appended.

Corn, F. App (New Jersey Stas. Circ. 69 (1917), pp. 7).—The advantages of an increased corn acreage under present food conditions are briefly discussed and the field practices employed in corn production in New Jersey outlined.

Varieties of cotton, 1916, W. E. Ayres (Arkansas Sta. Bul. 129 (1917), pp. 3-32, fig. 1).—Extensive variety tests with cotton at Scotts, Mena, and Fayetteville and cooperative tests throughout the State are reported, with considerable tabulated data.

The highest-yielding varieties at Scotts were Cleveland, with 946.2 lbs. of lint per acre, and Cook No. 920, with 813.8 lbs. per acre. At Mena Half and Half was first, with 265.4 lbs. of lint, and Arkansas Trice second, with 225.4 lbs. per acre. Brief descriptive data are submitted for the varieties tested at Fayetteville.

The recurving of milo and some factors influencing it, A. B. Conner and R. E. Karper (Texas Sta. Bul. 204 (1917), pp. 3-30, figs. 13).—Experiments were conducted by the authors during 1916 at Lubbock, Tex., pertaining to the recurving, or "goosenecking," of milo maize, which is deemed undesirable on account of the difficulty of harvesting the crop with machinery and the reduction in yield through loss of heads during the early stages of growth. Some conclusive data are presented on the anatomy of the milo maize plant and variation in anatomy of both milo maize and Kafir corn plants under different environmental conditions. No definite conclusions are drawn as to the fundamental causes of recurving, although a number of the factors which heretofore were considered responsible for the phenomenon have been eliminated and evidence advanced to indicate that recurving is due to the structure and development of the upper leaf sheath.

Considerable tabulated data are presented and discussed in detail. The studies are to be continued in the hope of obtaining a proper basis for the selection of strains having erect heads. The observations for the season of 1916 may be summarized as follows:

Tallness or dwarfness in the same strain was a result of the lengthening or shortening of the internode. No apparent difference was observed in the tenderness of the peduncle of different grain sorghums at similar stages of growth. Dwarfness was associated with a high percentage of erect heads, while tallness was attended by a high percentage of pendant heads. Rapid growth was conducive to tallness and slow growth to dwarfness.

The removal of a vertical section of the back of the upper leaf sheath always resulted in a complete recurving of the peduncle in the direction of the open-

ing. The upper leaf is attached to its sheath at an angle of approximately 45°, and the long side of the sheath first begins inrolling. Tall plants showed a long inroll of the upper sheath as compared with dwarf plants, that character being also associated with a large number of pendant heads.

Root pruning and a consequent limitation of the food supply increased the number of erect heads and decreased the number of pendant heads. Furthermore, a limitation of the moisture and food supply of the individual plants by reducing the feeding area per plant resulted in an increased number of erect heads and a decreased number of pendant heads.

Measurements of internode and sheath lengths in both milo maize and Kafir corn showed that while the internode lengths varied widely under different environmental conditions, the sheath length remained quite stable. A variation of the internode length without a corresponding change in the sheath length resulted in an overlapping of the internode in varying degrees when the same plant was grown under different conditions. Long overlapping of the sheath probably furnished support to the stem and the peduncle, while a short overlapping supplied correspondingly little support. The removal of the inrolled sheath tip before any part of the head appeared resulted in an increased percentage of erect heads. It appeared that in milo maize the tightly inrolled upper leaf sheath tip influenced the position of the head.

The culture of early potatoes under glass (Jour. Bd. Agr. [London], 23 (1917), No. 10, pp. 976-978).—This is a brief general discussion of the production of early potatoes under glass. Several early and second early varieties are recommended for use, and directions are given for the preparation of the soil, planting, and the care of the house during the growing season.

The morphology and development of transplanted rice, B. MARCARELLI (Gior. Risicolt., 6 (1916), Nos. 13-14, pp. 211-222; 22, pp. 341-347; 23, pp. 357-364; 24, pp. 372-378, figs. 21).—The morphology and development of transplanted rice is compared with that of rice seeded in the field. The author discusses in particular the morphological effects of transplanting on the root system, the aerial portions of the plant, stem development, and development of the rachis.

The increased development following transplanting is illustrated.

Studies of the volume weight of hulled rice grains, M. Kondo (Ber. Ohara Inst. Landw. Forsch., 1 (1916), No. 1, pp. 1-26, pls. 2).—This reports studies with rice to determine the correlation between volume weight and such grain characteristics as size and form of kernel, water content, mixture of whole and broken kernels, impurities, etc., since volume weight is a recognized factor in determining the value of rice on the Japanese market.

Similar studies with barley, wheat, rye, and oats are noted.

Considerable data are presented in tabular form and graphs drawn to illustrate the correlations studied.

In studying the relationship between the water content of hulled rice and its volume weight, the experiments included drying by the heat of the sun, drying in a desiccator with sulphuric acid or calcium chlorid, and drying in an oven. A fourth experiment was planned to study this relationship in hulled rice kernels which had been dried by the sun's heat before hulling.

The volume weight of hulled rice kernels is influenced by different factors, the relationship between volume weight and these factors being as follows: Factors causing an increase in volume weight were smooth seed coat; thick, round, short-elliptical kernels; the addition of small kernels; the mixing of large and small kernels of the same kind; and sun or oven drying of the seed before hulling. Factors which caused a decrease in volume weight were a rough seed coat; long, thin kernels; broken shrunken kernels, straw, chaff,

etc.; drying by the sun's heat or by means of chemicals; and the absorption of water. The one factor which exerted no definite influence was size of kernel.

The author concludes that in view of the complex nature of these correlations it is practically useless to attempt a determination of the quality or moisture content of rice by means of volume weight.

Rhodes grass, P. H. Rolfs (Florida Sta. Bul. 138 (1917), pp. 182-190, fg. 1).— The value of Rhodes grass for hay and pasture in central and southern Florida has been demonstrated by field tests at the station since 1909, and its use is recommended on well-tilled, moist lands in regions where the winter temperatures do not go below 23° or 22° F.

Sugar beet culture, R. L. Stewart (New Mexico Sta. Bul. 107 (1917), pp. 30, figs. 7).—The production of sugar beets in New Mexico is discussed in detail. The results of rather extensive experiments begun in 1916 are reported as planned to study the best cultural methods and the effect of low humidity and high temperature upon the yield and sugar content of the beets and the purity of the juice.

The experimental work was conducted on light sandy, silt loam, and moderately heavy adobe soils. Plantings were made on all sandy and adobe soils in December, January, and February, and on the silt loam beginning with March 15 and at 15-day intervals for the remainder of the season. Irrigation consisted of flooding after planting, furrowing after planting, or planting in a moist seed bed. The best stands were secured from plantings made May 1, while little difference was noted in the stands under different methods of irrigation.

Analyses of samples from the different plats gave an average of 13.1 per cent sugar and 79.1 per cent purity. The maximum sugar content was 20.3 per cent and the maximum purity 94.2 per cent.

The results of the first year's test indicate that beets grown on heavy soil are lower in sugar content and in purity than those grown on light soils.

The tillering of winter wheat, A. E. Grantham (Delaware Sta. Bul. 117 (1917), pp. 3-119, figs. 18).—An extensive study of tillering of winter wheat is reported in an effort to determine to what extent certain factors affected the rate of tillering and, through tillering, the yield of grain. The studies included an investigation of (1) the effects of environmental factors on tillering, such as time, rate, and depth of seeding and fertilization, (2) of the relation of heredity to tillering, including the relation of variety to tillering, and the inheritance of tillering, and (3) a study of the number of tillers in relation to length of culm, length of spike, yield per plant, yield per spike, and quality of grain. Considerable tabulated data are presented, discussed in detail, and may be briefly summarized as follows:

The time of seeding directly influenced tillering, early seeding being accompanied by a higher rate of tillering than late seeding. The yield per spike of high-tillering plants usually exceeded that of low-tillering plants.

Rate of seeding influenced tillering in that the thicker the seeding the fewer the tillers per plant. Close seeding resulted in earlier maturity and shorter spikes. A high seeding rate lessened the number of tillers, the length of culm and spike, and the yield of grain in smooth wheats to a greater extent than in bearded wheats.

Nitrogen and phosphoric acid appeared to stimulate tillering, while potash had little or no effect. Wheat was observed to tiller equally as well when sown late on fertile soil as when sown earlier on thin soil.

The capacity for tillering appeared to be a variental characteristic, varieties differing considerably in this respect. Bearded wheats as a class tillered more freely than smooth wheats, the environmental factors appearing to influence the

rate of tillering in the former to a less extent. A tendency was noted for high tillering mother plants to produce a larger proportion of plants with a larger number of tillers than the average, but the inheritance of tillering as indicated by the performance of individual plants was not marked.

Increased yields per spike accompanied an increase in the number of tillers per plant up to 4 or 5 tillers, beyond which the yield was more or less uniform. Low tillering plants of a variety produced smaller yields per spike and grain of poor quality. Within a variety under similar conditions of planting the quality of grain was correlated to some extent with the number of tillers per plant. Varieties with coarse, stiff straw did not tiller so freely as those with finer, more pliable straw. Depth of planting did not appear to affect materially the number of tillers per plant. The improved quality of grain used for seed, as indicated by size, plumpness, and weight, favored a higher rate of tillering.

Regulations and instructions relating to the labelling, inspection, and analysis of seeds in New Jersey, J. P. Helyar (New Jersey Stas. Circ. 66 (1917), pp. 3-10).—This outlines the rules and regulations promulgated by the station for the enforcement of the New Jersey seed law of 1916.

The seed situation, J. P. Helyar (New Jersey Stas. Circ. 72 (1917), pp. 3-7).—This is a brief consideration of the most feasible means for meeting the situation in respect to agricultural seeds for the 1918 planting.

### HORTICULTURE.

Gardening.—A complete guide, H. H. Thomas (London and New York: Cassell & Co., Ltd., 1917, pp. [8]+152, figs. 78).—A guide to the culture of ornamentals, fruits, and vegetables, both in the open and under glass.

The beginner's gardening book, H. H. THOMAS (London and New York: Cassell & Co., Ltd., 1917, pp. 80, flgs. 18).—A small popular treatise on ornamental and kitchen gardening.

The manuring of market garden crops, with special reference to the use of fertilizers, F. T. Shutt and B. L. Emsle (Canada Expt. Farms Bul. 32, 2. ser. (1917), pp. 36).—This bulletin deals briefly with some of the important features of market gardening in Canada, with special reference to the selection and use of fertilizers and fertilizing materials. Data on fertilizer experiments with vegetables conducted in 1915 are appended. The results as a whole indicate the economic advantage of a medium application of manure with suitable commercial fertilizers as compared with the use of a large quantity of manure alone.

Possibilities of the fall vegetable garden, C. E. Durst (Illinois Sta. Circ. 200 (1917), pp. 8, fig. 1).—This circular deals with vegetables which can be made available for fall use. Consideration is given to vegetables planted in early spring and which are capable of surviving hot dry weather, vegetables planted in late spring and early summer, and quick maturing vegetables planted in late summer or early fall especially for fall use.

Variety tests of potatoes, tomatoes, cabbage, and other vegetables, T. H. White (Maryland Sta. Bul. 204 (1917), pp. 231-262, figs. 5).—This bulletin contains the hitherto unpublished notes and records of vegetables that have been tested at the station during the past ten years.

Potatoes and root crops, H. H. Thomas (London and New York: Cassell & Co., Ltd., 1917, pp. 80, flys. 23).—A small popular treatise on the culture of potatoes and other garden root crops.

Tomatoes and salads, H. H. Thomas and F. R. Castle (London and New York: Cassell & Co., Ltd., 1917, pp. 79, figs. 27).—A small popular treatise on the culture of tomatoes and various salad plants.

Harvesting and storing vegetables for home use, J. J. GARDNER (Colorado Sta. Bul. 232 (1917), pp. 3-7, figs. 3).—Suggestions are given relative to time of planting and harvesting with reference to storing vegetables, together with directions for storing home supplies of the more common vegetables.

Commercial onion culture in Idaho, C. C. VINCENT (Idaho Sta. Bul. 97 (1917), pp. 3-16, figs. 9).—This bulletin embodies the results of variety and cultural tests conducted at the station during the last three years, together with the cultural methods followed by the largest and most successful onion growers in the State.

Studies on the dying out of pepper vines in the Dutch East Indies.—III. Pepper cultivation in the Lampong district, A. A. L. RUTGERS (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 27 (1916), pp. 65, pls. 14).—This is the third report (E. S. R., 35, p. 835) on a study of the causes leading to the dying out of pepper vines in the Dutch East Indies.

The author concludes in substance that the dying out prematurely can not be explained by the action of insect and fungus troubles but is rather to be attributed to the general state of cultivation. The indications are that with proper methods of tillage, manuring, and other cultural measures peppers may be successfully grown on soils where they have been regularly dying out prematurely.

Report on the Government Horticultural Gardens, Lucknow, for the year ended March 31, 1917, H. J. Davies ( $Rpt.\ Govt.\ Hort.\ Gardens\ Lucknow,\ 1917,\ pp.\ [6]+10).—A brief statement relative to the condition of various fruits and other economic plants grown at the gardens, including a financial statement for the year.$ 

Fifteenth annual report of the State nursery inspector, H. T. Fernald (Agr. of Mass., 64 (1916), pt. 1, pp. 69-97, pls. 4).—A report of activities during 1916, with special reference to the inspection of nursery stock for the detection and control of the gipsy and brown-tail moths and white pine blister rust.

Factors governing fruit bud formation, B. T. P. BARKER and A. H. LEES (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1916, pp. 46-64, figs. 4; Jour. Bath and West and South. Counties Soc., 5. ser., 11 (1916-17), pp. 171-191, figs. 4).—A discussion of various factors affecting fruit bud formation, including a summarized report on long-continued pruning investigations with several varieties of apples conducted at the Agricultural and Horticultural Research Station of the National Fruit and Cider Institute. Long Ashton, Bristol.

Thus far no definite conclusions are reached relative to the direct effect of pruning on fruit bud formation. The evidence secured indicates that both heavy and light winter pruning have given practically the same number of laterals and fruit buds, although these were distributed differently on the trees, the light pruned trees showing a greater amount of growth but much more bare wood.

A study of meteorological conditions prevailing at Long Ashton led the authors to conclude that any results secured from pruning are of only a local value and that the question of fruit bud formation should be investigated with the idea of determining the ultimate cause. Among the factors to be studied in continuing the work are excess of water in the soil, deficiency of water in the soil, the effect of artificial manures, light, and shade.

Miscellaneous notes on experiments in fruit culture, B. T. P. BARKER, A. H. Lees, and G. T. Spinks (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1916, pp. 71-73; Jour. Bath and West and South. Counties Soc., 5. ser., 11

(1916-17), pp. 196-198).—The notes here given deal with the progress being made in fruit-breeding investigations at Long Ashton, Bristol, experiments in planting different aged plum trees and the influence of stock on fruit trees. Thus far no definite conclusions have been drawn.

Methods of handling basket fruits, E. SMITH and J. M. CREELMAN (Canada Dept. Agr., Dairy and Cold Storage Branch Bul. 52 (1917), pp. 13, figs. 10).—
The methods here described are based primarily on data obtained in the operation of the Dominion precooling and experimental fruit-storage warehouse at Grimsby, Ont.

A systematic study of Iowa apples, L. R. HARTILL (*Trans. Iowa Hort. Soc.*, 51 (1916), pp. 162-248).—A paper on this subject prepared for the Iowa State College and State Horticultural Society, and comprising a descriptive list of the more important varieties of apples grown in Iowa. A list of cited literature is included.

Fertilizer experiments on apple trees at Highmoor Farm, C. D. Woods (Maine Sta. Bul. 260 (1917), pp. 99-102).—A brief statement of progress made on long-continued experiments being conducted by the station.

Experiments to determine the value of highly nitrogenous fertilizers as a means of forcing trees into bearing have thus far shown no differences that could be attributed to the additional nitrogen in the fertilizer. Experiments conducted since 1912 appear to confirm partially the results secured at the New York State Station in which the use of fertilizers did not materially affect the yield and growth of apple trees (E. S. R., 25, p. 643). In the present investigation no differences could be observed between the trees fully fertilized, those partially fertilized, and those not fertilized at all during the past three years. On the other hand, the limited data available relative to yield of these trees indicate larger yields on the fertilized plats and a consistent increase with the amount of fertilizer applied. The experiment is to be continued for a number of years.

Winter v. summer pruning of apple trees, C. C. VINCENT (Idaho Sta. Bul. 98 (1917), pp. 28, pls. 2, figs. 23).—This bulletin gives the results secured for a period of 11 years in a comparative test of winter and summer pruning. The four varieties included in the test were Jonathan, Rome, Grimes, and Wagener. The winter-pruned trees received a moderate annual pruning during the dormant season from the time the trees were planted in 1905 until the present time. Similar pruning in the summer-pruned plat took place after the terminal growth had stopped for the year. A complete record of the yields of each individual tree in both plats is given from the time the trees commenced bearing until the present time. Observations were also made on color and growth performance.

On the basis of the total production for the first seven crops summer pruning has produced the greatest yield in all varieties. Color in the three red varieties was intensified by summer pruning. As determined by both color and yield, the crop value per acre under summer pruning as compared with winter pruning shows an average gain of \$52.33 for Jonathan, \$53.64 for Rome, and \$30.69 for Wagener. In some cases summer pruning has hastened the bearing of the young trees. Summer pruning increased the average terminal growth somewhat but tended to check the total wood growth slightly. The average diameter of the tree trunks in the winter-pruned plat was somewhat larger. The experiment as a whole shows that thinning has a direct relation to pruning and crop production.

Field experiments in spraying apple orchards, B. S. Pickett et al. (*Illinois Sta. Bul. 185*, abs. (1916), pp. 12, figs. 4).—A popular edition of Bulletin 185, previously noted (E. S. R., 35, p. 39).

Modern methods of packing apples, A. H. Flack and P. J. Caret (Canada Dept. Agr., Fruit Branch, Fruit Comr. Ser. Bul. 2 (1917), pp. 62, figs. 57).— This bulletin gives instructions for packing apples in boxes and barrels, the subject matter being largely a revision of previous information on the subject (E. S. R., 19, p. 741).

Preliminary report on apple-packing houses in the Northwest, W. M. Scorr and W. B. Alwood (U. S. Dept. Agr., Off. Markets and Rural Organ. Doc. 4 (1917), pp. 31, figs. 9).—This comprises a preliminary report on an investigation conducted in the States of Washington and Oregon during the apple packing season of 1916, with reference to the handling of apples from the orchard to and through the packing house and into the cars ready for shipment to market.

The subject matter is presented under the general headings of community packing houses, community packing-house equipment, packing-house organization and personnel, a suggested floor unit, some of the details of operation, and the operations in two typical houses.

Plum growing in Maryland, F. S. Holmes (Maryland Sta. Bul. 207 (1917), pp. 295-326).—This bulletin presents information relative to the status of the plum growing industry in Maryland and gives the results with varieties tested at the station, together with brief suggestions on orchard management, picking, packing, and marketing.

Profitable small fruits, H. H. THOMAS (London and New York: Cassell & Co., Ltd., 1917, pp. 80, figs. 25).—A popular treatise on the culture of strawberries and bush fruits.

The strawberry in North America, S. W. Fletcher (New York: The Macmillan Co., 1917, pp. XIV+234, figs. 26).—A companion work to the author's treatise on strawberry growing (E. S. R., 37, p. 42), and dealing mainly with the origin and history of the North American type of strawberries, including information relative to the improvement of strawberries by breeding and the development of commercial strawberry growing. A list of breeders since 1854 is given.

Soil influence on the composition of strawberries, C. T. GIMINGHAM (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1916, pp. 65-70; Jour. Bath and West and South. Counties Soc., 5. ser., 11 (1916-17), pp. 191-196).—The results secured with two varieties of strawberries as grown on several different types of soil in the three years, 1914 to 1916, at Long Ashton, Bristol, are here presented.

Among the general conclusions thus far deduced it was found that the two varieties tested show a marked variety distinction in respect to degree of acidity. As to sugar content seasonal influence appears to outclass other factors. With one or two exceptions no soil effect was sufficiently pronounced in the trials to show itself in the presence of the other factors concerned.

The study is to be continued.

New or noteworthy tropical fruits in the Philippines, P. J. WESTER (Philippine Agr. Rev. [English Ed.], 10 (1917), No. 1, pp. 8-23, pls. 9).—In continuation of previous papers (E. S. R., 34, p. 639) the author describes and gives notes on a number of tropical fruits which have been tested at the Lamao Experiment Station.

Report on manurial experiments (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Dominica, 1916-17, pp. 45-58, pl. 1).—This is the customary progress report on manurial experiments with cacao and limes in Dominica (E. S. R., 36, p. 141). The data secured on the various plats are presented in tabular form and discussed. Work on the lime plats was interfered with by hurricanes in 1916 and the experiments have been reorganized. The results to date are similar to those previously noted.

Citrus experimental grove, S. E. Collison (Florida Sta. Rpt. 1916, pp. 113-118).—In continuation of previous reports (E. S. R., 35, p. 839) measurements are given showing the average gain in diameter of trees from June, 1909, to June, 1916, growing on the various fertilizer plats in the citrus experimental grove. The lime requirements as studied for each plat are also presented in tabular form.

The data secured show that the acidity of the plats varies from season to season, being greatest in summer and least in winter. The greater increase in acidity during the summer is attributed to the increased decay of vegetable matter. Plats receiving strongly alkaline materials, such as lime, limestone, and hardwood ashes were alkaline in reaction, and those receiving mildly alkaline materials such as Thomas slag and nitrate of soda showed a decrease in acidity. The use of phosphoric acid from floats has not served to decrease the acidity of the soil.

Do fertilizers influence the composition of oranges? H. J. Webber (Cal. Citrogr., 2 (1917), No. 6, pp. 17-19).—A brief analysis of experiments previously reported by H. D. Young (E. S. R., 36, p. 642).

Standards of maturity for the Washington navel orange, E. M. CHACE (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 8, pp. 325-330).—The substance of this article has been noted from another source (E. S. R., 37, p. 345).

Some notes on frost protection in orange groves, R. S. VAILE (Cal. Citrogr., 2 (1917), No. 6, pp. 10, 11, 16).—A paper on this subject read at the Orange Show Convention, in which the author reviews the work of various citrus associations and individual growers in protecting groves from frost and makes some deductions relative to the value of frost-protective methods,

It is concluded in brief that although it is entirely possible to protect orange groves against frost it may or may not be profitable, depending upon the size of the crop, amount of actual risk, and amount of protection necessary for any particular grove. It is believed that more attention should be given to the adding of heat units than to the prevention of radiation by the formation of a cloud of smoke.

Preventing frost damage in transit, A. W. McKay (Col. Citrogr., 2 (1917), No. 6, pp. 4, 5, 17, figs. 4).—The results of experiments conducted by the U. S. Department of Agriculture during two seasons to determine means of preventing frost injury to citrus fruits in transit are here reported.

Effect of different methods of transplanting coffee, T. B. McClelland (Porto Rico Sta. Bul. 22 (1917), pp. 11, pl. 1).—This bulletin reports the result of a trial test of different methods of transplanting coffee, shows the advantages and disadvantages of each method, and gives suggestions relative to the correction of bad practices.

Briefly stated, the test shows that the transplanting of moderately large coffee seedlings, either from or into a heavy clay soil, should unquestionably be done with the roots still incased in the soil in which they grew.

A preliminary report on some breeding experiments with foxgloves, E. Warren (Biometrika, 11 (1917), No. 4, pp. 303-327).—A discussion of the results secured in a number of first generation crosses.

#### FORESTRY.

Second biennial report Nebraska Forestation Commission, C. Rohde, A. H. Metzger, and W. Ball (*Bien. Rpt. Nebr. Forestation Com.*, 2 (1916), pp. 19).—This report contains recommendations and outlines of proposed legislation dealing with forestry in Nebraska.

Report of the State forester and firewarden, C. P. Wilber (Rpts. Dept. Conserv. and Develop., N. J., 1916, pp. 49-84, pls. 9, figs. 2).—A brief statement of activities during the year, including a description of the forests of the State forest reserves and detailed information relative to fire protective work.

Report of the chief forest firewarden for the year 1916, G. H. Wirt (Penn. Dept. Forestry Bul. 16 (1917), pp. 123, pls. 3, figs. 3).—A report on forest protective measures in Pennsylvania during 1916, including data on forest fires for the year.

Report of the forest branch of the department of lands for the year ended December 31, 1916 (Rpt. Forest Branch Dept. Lands, B. C., 1916, pp. 35, flgs. 2).—This report deals with the development of markets for British Columbia lumber, together with statistics on sawmill operations, lumber cut, timber sales, fire protection, and miscellaneous work conducted during 1916.

French forests and forestry.—Tunis, Algeria, Corsica, T. S. Woolsey, Jr. (New York: John Wiley & Sons, Inc., 1917, pp. XV+238, figs. 20).—The author here presents the results of a study of the more important phases of forest practice in Corsica, Algeria, and Tunis and a translation of the Algerian forest code of 1903. A subsequent work will be descriptive of methods employed in the forests in France proper. In presenting the subject matter as a whole the aim has been to set forth the essentials of method which may be applied directly in the United States or which may be indirectly of value to English-speaking foresters.

Report on forest operations in Switzerland (Rap. Dépt. Suisse Int., 1916, pp. 1-12).—The usual report (E. S. R., 35, p. 543) relative to the administration and management of State, communal, and private forests in Switzerland, including data on forest products, revenues, expenditures, etc., in 1916.

Annual progress report of forest administration in the United Provinces for the forest year 1915–16, H. G. Billson (Ann. Rpt. Forest Admin. United Prov., 1915–16, pp. 27+LXX+[7]).—The usual report relative to the administration and management of the State forests in the United Provinces. All important data relative to alterations in forest areas, forest surveys, working plans, miscellaneous work, yields in major and minor forest products, revenues and expenditures, etc., are appended in tabular form.

Progress report of forest administration in the Jammu and Kashmir State for the year 1915-16, B. O. COVENTRY (Rpt. Forest Admin. Jammu and Kashmir [India], 1915-16, pp. II+26+LV).—A report similar to the above on the administration and management of the State forests in Jammu and Kashmir State.

Progress report of forest administration in Coorg for 1915-16, H. TIREMAN (Rpt. Forest Admin. Coorg. 1915-16, pp. [4]+11+13).—A report similar to the above, relative to the administration and management of the State forests of Coorg for the year 1915-16.

Administration report of the forest circles in the Bombay Presidency, including Sind, for the year 1915-16 (Admin. Rpt. Forest Circles Bombay, 1915-16, pp. II+172+6).—A report similar to the above relative to the administration and management of the State forests of the Northern, Central, Southern, and Sind Circles in the Bombay Presidency for the year 1915-16.

Notes on the principal timbers of Queensland (Dept. Pub. Lands, Queensland, Forestry Bul. 2 (1917), pp. 20).—Notes are presented on the more important timbers of Queensland with reference to their distribution, general characteristics, uses, strength, and durability.

Georgia forest trees (Forest Club Ann., Ga. State Forest School, 1917, pp. 69, flgs. 70).—A handbook describing the coniferous and hardwood trees of Georgia. A key to the hardwoods is included.

Reproduction in the coniferous forests of northern New England, B. Moore (Bot. Gaz., 64 (1917), No. 2, pp. 149-158).—A paper on this subject delivered at the meeting of the Ecological Society of America in New York City in December, 1916, in which the author gives the results of an investigation undertaken to determine the factors governing the reproduction of the more important coniferous trees in the forests of northern New England. A bibliography of literature cited is included.

Growth study of planted trees, H. DORR, JR., and W. A. BOAG (Forestry Ann. [Mich. Agr. Col.], 2 (1917), pp. 37, 38).—A table is given showing the growth performance of various hardwood species planted in 1909 in the forest nursery of the Michigan Agricultural College.

Frustum form factor volume tables for sugar maple, E. G. Hamlin (Porestry Ann. [Mich. Agr. Col.], 2 (1917), pp. 14-18, fig. 1).—The tables here presented were prepared with a view to determining the feasibility and accuracy of the frustum form factor method in preparing volume tables. The data were secured in Wexford County, Mich., during 1915 and 1916.

A study of breakage, defect, and waste in Douglas fir, E. J. Hanzlik, F. S. Fuller, and E. C. Erickson (Univ. Wash. Forest Club. Ann., 5 (1917), pp. 32-40, fig. 1).—A short study was made in the spring of 1916 to secure data upon breakage, defect, and waste in logging Douglas fir timber. The results are here presented in tabular form and are supplemented by a report on breakage in Douglas fir timber as observed in three typical logging camps during 1915.

On the influence of the age of the trees on the quality of the rubber, O. DE VRIES (Arch. Rubbercult. Nederland. Indië, 1 (1917), No. 3, pp. 169-177).—A number of special experiments were conducted to determine the influence of the age of rubber trees on the quality of the rubber.

The results in general show that the tensile strength of rubber from older trees is not appreciably better than from young trees. The slope or type of the stress strain curve is generally the same, although sometimes somewhat better for old trees. The rate of cure diminishes in an appreciable degree with the age of the tree and the viscosity for old trees is nearly always better.

The preservative treatment of poles, B. L. Grondal (Univ. Wash. Forest Club Ann., 5 (1917), pp. 8-11, fig. 1).—In this paper the author discusses modern methods of treating poles, including the recently developed perforation process in which the poles are pierced in a number of places to insure greater penetration of creosote just above and just below the ground line where fungi are most active.

Mapping methods, C. M. Cade (Forestry Ann. [Mich. Agr. Col.], 2 (1917), pp. 19-24, fig. 1).—A discussion of present practice in mapping land areas, including forest tracts.

## DISEASES OF PLANTS.

Report of the associate plant pathologist, C. D. Sherbakoff (Florida Sta. Rpt. 1916, pp. 80-98, figs. 5).—The line of investigations reported upon is similar to that previously noted (E. S. R., 35, p. 844), including studies of diseases of vegetables and a disease of pineapples.

Chief attention has been paid to damping-off of seedlings, *Rhizoctonia* sp. being the most troublesome fungus in Florida in this respect. Experiments in the control of damping-off have been carried on, and the application of 0.5 per cent copper sulphate solution has given good results with lettuce, the seeds germinating normally and no damping-off following. For seed disinfection, formalin and corrosive sublimate have been compared, the author having found in the use of corrosive sublimate with a number of kinds of seeds, particularly

celery, that the temperature of the solution bears an important relation to the amount of injury produced.

A brief description is given of a rot of tomato fruit due to an undetermined species of Phytophthora. This disease, which is called buckeye rot, is to be the subject of a special publication. Brief notes are given on bacterial diseases of celery, lettuce, peppers, tomato, and potato, and on fungus diseases of a number of other vegetables.

In connection with the pineapple wilt studied by the author, in which study field observations and laboratory experiments were carried on, nematodes were found in almost every instance to be the cause of some of the injury. In addition to nematodes, *Thielaviopsis paradoxa* was found to attack the roots and stems of pineapples, causing considerable loss.

Report of the laboratory assistant in plant pathology, J. Matz (Florida Sta. Rpt. 1916, pp. 99-112, figs. 7).—The author reports upon his investigations on pecan dieback and the leaf blight of the fig.

The investigations of the dieback are in continuation of those previously described (E. S. R., 35, p. 849). Experiments in controlling the organism, Botryosphæria berengeriana, have been continued, and pruning dead wood from the trees has been found satisfactory in keeping down the disease. Spraying with lime-sulphur solution did not seem to have any effect.

The leaf blight of fig is described as characterized by a yellowish, water-soaked appearance on both surfaces of the leaves. The twigs and fruit may be infected by the spreading mycelium, although the blight is primarily one of the leaves. An organism has been isolated which experiments have shown to be the cause of the trouble and which has been determined as Rhizoctonia microsclerotia n. sp.

[Plant diseases in New Jersey, 1915], M. T. Cook (Ann. Rpt. N. J. Bd. Agr., 43 (1916), pp. 48-54).—Besides notes on plant diseases, 214 of which were observed during 1915, and mention of the four epidemics of economic diseases occurring in New Jersey during the year, namely, fire blight of pear and apple, anthracnose of bean, mosaic of tomato, and Rhizoctonia of potato, the author reports more specifically on potato diseases, including scab, leaf roll, blackleg, discolorations (Fusarium oxysporum and F. radicicola), and powdery scab (Spongospora subterranea), also on some preliminary experiments regarding the control of the diseases, the results of which varied considerably. The administrative report for 1915 of the State plant pathologist is included.

[Fungus pests and their control] (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Vincent, 1915-16, pp. 24-30).—The information here given relates to both insect enemies (particularly thrips on cacao) and fungus diseases of plants, with a discussion of conditions and remedial measures. Specimens were examined of arrowroot rhizomes affected with the so-called burning disease, which appears to be due to Rosellinia bunodes. Internal boll disease of cotton is thought to be related to the presence of cotton stainers.

Some parasitic fungi of Japan, T. Hemmi (Bot. Mag. [Tokyo]. 30 (1916), No. 358, pp. 334-344, figs. 5).—A discussion is given of Clasterosporium degenerans on Prunus mume, Septoria perila on Perilla ocimoides, and Armatella litsea on Litsea glauca, and a discussion with technical descriptions of the new species Septoglaum niisima on Quercus dentata and Septoria petasitidis on Petasites japonica.

Combating nematodes by the use of calcium cyanamid, J. R. Watson (Florida Sta. Rpt. 1916, pp. 55-63).—In addition to a previous account (E. S. R., 37, p. 453), the author describes experiments in the use of calcium cyanamid for the control of nematodes, particularly with tomatoes, peach trees, and pineapples.

Tomato plants were so badly burned as to be practically worthless when placed in the soil nine days after the application of the cyanamid. A second crop planted after an interval of about four months gave a fair crop of tomatoes, while plants in check plats yielded nothing. Nematodes were found in all the plats. Experiments in which cyanamid was applied at the rate of 1,500 lbs. per acre on light soil, and in which tomato plants were set out at once, showed that while the plants were severely burned, they recovered, made good growth, and were nearly free from nematodes. These experiments seem to indicate a correlation between the character of the soil and the amount of cyanamid used.

Where cyanamid was applied to peach trees at the rate of 1 to 6 lbs. per tree, it was found to reduce the number of nematodes present, although not penetrating the soil readily.

With pineapples, it was found that cyanamid could be applied at the rate of 1,500 lbs. per acre without injuring the plants, the nematodes being fewer than on untreated plants and the pineapples having a better color, probably due to the nitrogen of the fertilizer.

A new disease of wheat, E. F. SMITH (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 1, pp. 51-54, pls. 5).—The author reports the occurrence of a disease of wheat that has appeared in Indiana, Arkansas, Kansas, Missouri, Oklahoma, and Texas, and is believed to be present in other States. Numerous bacteria have been found associated with this disease, and while not definitely claiming that it is a bacterial disease, the author believes it to be of bacterial origin. A description is given of infected parts of plants, and attention is called to the disease in the hope that material may be forwarded to the author for further study.

Observations on stalk disease of wheat, J. Capus (Bul. Soc. Path. Veg. France, 2 (1915), No. 2, pp. 94-104).—Giving the results of observation and experimentation on Leptosphæria herpotrichoides, as causally connected with the appearance of foot or stalk disease in wheat, the author states that the trouble is favored by the susceptibility of some varieties, by soil and atmospheric humidity and warmth (during winter and early spring), by close seeding, by the presence of weeds, and probably by continued seeding of the same land to wheat.

Sulphuric acid in dilute solution, when used in early spring, kills the lower leaves and sheaths, admitting air and sunshine, both of which are unfavorable to the development of the foot or stalk disease fungi. This treatment is helpful if used during latency or imminence of the disease, but not markedly so after the attacks are well developed.

Common diseases of cucumbers and melons, W. H. MARTIN (New Jersey Stas. Circ. 68 (1917), pp. 11, figs. 5).—Popular descriptions are given of a number of the more common fungus and bacterial diseases to which cucurbitaceous plants are subject, together with suggestions for their control so far as definite means are known.

A form of potato disease produced by Rhizoctonia, G. B. RAMSEY (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 12, pp. 421-426, pls. 4).—In this contribution from the Maine Experiment Station the author gives a description of a type of potato tuber disease observed for the first time in southern Maine a few years ago. No positive evidence has been found of the trouble in northern Maine nor any reference to this form of injury elsewhere in the country.

Two phases of injury are produced by the fungus, one whose external appearance somewhat resembles scab and which extends as a dry core into the tuber, another in which the shrinkage of tissues has formed a pit or canal in the center of the infected area, frequently suggesting wireworm injury. His-

tological studies in all stages of the progress of the disease show the presence of Rhizoctonia, and pure cultures of the fungus have been repeatedly obtained from the interior of the diseased areas. Evidence is presented that indicates that the host cells die and lose their contents and the walls suberize and are more or less broken down in advance of the fungus filaments. This, the author states, might lead to the supposition that part of the action is due to a toxin secreted by the fungus. Cell wall penetration by the hyphæ is thought to occur, but this is believed to be the exception rather than the rule.

A new strain of Rhizoctonia solani on the potato, J. Rosenbaum and M. Shapovalov (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 12, pp. 413-420, pls. 2, figs. 3).—A description is given of a strain of R. solani which was isolated from the stems of potatoes in Maine during the summer of 1916. This strain is distinguished from the more common form of R. solani by the more pronounced lesions produced when inoculated on injured stems or tubers; by the reaction, growth, and character of sclerotia on definite media; and, morphologically, by measurements of the mycelium, also of the short sclerotial cells, and by the measurement of the diameter of germ tubes when the short, or barrel-shaped, cells enveloping the sclerotia are placed in drops of water to germinate.

An investigation of the potato rot occurring in Ontario during 1915, D. H. Jones (Abs. Bact., 1 (1917), No. 1, pp. 37, 38).—Reporting briefly the result of studies made during 1915 and 1916, the author states that potato diseases are greatly favored by such continued wet weather as prevailed during 1915. Rhizoctonia was the principal and soft rot bacillus the secondary cause of the black basal stem rot and collapse which occurred in many places during 1915, the organism producing only a slightly shrunken, brown canker where the cortical tissue alone was punctured. The soft rot bacillus could not penetrate healthy, unbroken epidermal tissue, but when introduced beneath the punctured epidermis of a young potato stem or tuber, or of carrot, turnip, or cauliflower, it produced a characteristic soft rot. Seed tubers showing sclerotia of Rhizoctonia (black scab) are most likely to give a diseased crop unless disinfected, which may be done by soaking them in water for two or three hours and then in 0.1 per cent corrosive sublimate for five or six hours.

Fusarium sp. caused much of the tuber rot observed at harvesting time and in storage. The disease may be carried over in débris of the potato crop left in the soil, high humidity favoring its development.

Diseases of tomatoes, M. T. Cook and W. H. Martin (New Jersey Stas. Circ. 71 (1917). pp. 8, figs. 6).—The authors briefly describe the more prevalent fungus, bacterial, and other diseases of tomatoes, and offer suggestions for their control.

Apple blotch and its control, J. W. ROBERTS (U. S. Dept. Agr. Bul. 534 (1917), pp. 11, pls. 2, figs. 3).—The author describes the blotch of fruit, foliage, and twigs of the apple due to the fungus Phyllosticta solitaria, and gives the results of his investigations on the disease and on methods of control. His cross-inoculation experiments are said to confirm the inoculation work of Scott and Rorer (E. S. R., 20, p. 1044).

As an explanation for the few infections which occur late in the season, the author suggests an increased resistance of the host as well as a gradual decrease in the number of spores produced by the fungus. A large number of mummied fruits were examined throughout the spring but no spores were found, and hence the author concludes that mummies are not an important source of infection.

It is claimed that apple blotch may be controlled by three sprayings with 3:4:50 Bordeaux mixture applied at intervals of three weeks, the first spray

being applied about three weeks after the petals have fallen. Summer-strength lime-sulphur solution may be substituted for Bordeaux mixture where the disease is not severe, thus lessening the risk of injury.

Apple scab control in British Columbia, R. M. Winslow (Canad. Hort., 40 (1917), No. 2, pp. 32, 56-58, fig. 1).—The rapid spread of apple scab in British Columbia during the last three years is said to have caused much alarm, discouraging some very careful growers. In view of the losses of 1915, an extensive series of tests was carried out in 1916 with lime-sulphur, which was applied when the leaves were from ½ to ½ in. in length, when the blooms were just about to open, when the blooms were falling, and again 14 days later, the last three of these sprays proving to be of the greatest general utility. A wet July makes a summer spray advisable, in addition to those above mentioned. An abnormally bad year for scab may be followed by one almost free therefrom. The sprays increased the percentages of absolutely clean and marketable fruit, the average weight of the fruit, the total yield, the set of fruit, and the vigor of the foliage. Tests with Bordeaux mixture and with atomic sulphur gave less favorable results than those with lime-sulphur, which gave fair control of scab even when unsprayed trees showed from 98 to 100 per cent infection.

The biology of Exoascus deformans, A. Manaresi (Riv. Patol. Veg., 7 (1915), No. 7, pp. 193-201).—The author during 1912 to 1915 made a study of several varieties of peach in the Province of Bologna as affected by E. deformans, the cause of leaf curl, in connection with the weather during that period and the treatments employed. The results are tabulated and discussed. Strong Burgundy mixture applied about the middle of March gave good results, later applications being ineffective.

Comparative resistance of Prunus to crown gall, C. O. SMITH (Amer. Nat., 51 (1917), No. 601, pp. 47-60, figs. 6).—This is a more detailed account of the work already noted (E. S. R., 36, p. 352).

Winter injury of grapes, F. E. GLADWIN (New York State Sta. Bul. 433 (1917), pp. 107-139, pls. 8).—As a result of a study of light crops of grapes during the years 1909 to 1916, the author was led to the conclusion that such crops are due to injury to immature shoots by low temperatures. Embryo flower clusters were found to be injured by low temperatures if they entered the dormant period immature, yet the foliage of the bud might expand normally. The effect of low temperatures following various periods when temperatures rose high enough and continued for sufficient time to start activity is discussed.

Experiments testing the effect of various fertilizer elements on maturity indicate that neither nitrogen, phosphoric acid, nor potash influenced maturity, and hence their effect was not apparent as influencing the degree of killing. The extent of injury was observed to be closely correlated with poor drainage of soils, although some killing occurred where drainage was reported as satisfactory. Severe pruning after late frost injury in the spring is believed to favor bud killing indirectly through inducing rank wood growth. Maturity of bud and wood is probably correlated with the ripeness of the fruit, as determined from sugar analyses of the fresh juice.

Resistance to low temperature is considered a species character and is possibly correlated with hardness of wood.

Why and when winter kills grapes, F. H. Hall (New York State Sta. Bul. 433, popular ed. (1917), pp. 3-8, figs. 4).—A popular edition of the above.

A fatal disease of mulberry, L. Montemartini (Riv. Patol. Veg., 7 (1915), No. 8-9, pp. 238-242).—The results to date of the inquiry regarding a disease of mulberry (E. S. R., 33, p. 448) in seven Provinces have already shown it to be

widely diffused and of considerable importance, but not so severe on clayey and limy soils as on some others indicated.

Anthracnose of Japanese persimmon, L. MAFFEI (Riv. Patol. Veg., 7 (1915), No. 6, pp. 161-163).—A brief description is given of a disease of fruits of Japanese persimmon in the botanical garden at Pavia, caused by Glassporium kaki.

Report of the plant physiologist, B. F. FLOYD (Florida Sta. Rpt. 1916, pp. 30-50, flgs. 6).—This report gives the results of a study of the toxic effect of certain organic chemicals on citrus and of injury to citrus trees by ground limestone.

Previous investigations (E. S. R., 29, p. 248) having shown that dieback of citrus trees could be induced by organic nitrogenous fertilizers, the author reports on experiments to test the action of vanillin on both citrus seedlings and citrus cuttings. This organic compound was added to nutrient solutions used at various rates in the growth of seedlings, and, while marked injury to the roots was produced, no gum, which is characteristic of the disease dieback, was formed in grapefruit seedlings. With citrus cuttings vanillin produced no gum, but, as no gum was formed in a series of experiments in which copper sulphate was used, it is believed that the lack of gum formation in cuttings may have been due to the absence of growth.

The attention of the station having been called to apparent injury in a number of groves where ground limestone had been applied, an investigation was made. Pot experiments indicated that ground limestone can, under limited conditions, induce injury to citrus trees, and that this injury shows itself by a frenching, or chlorosis, of the foliage of the trees.

Some cases of injury to citrus trees apparently induced by ground limestone, B. F. Floyd (Florida Sta. Bul. 137 (1917), pp. 161-179, figs. 6).—This bulletin is essentially a reprint from the article noted above, with suggestions for the control of the injury.

Report of the plant pathologist, H. E. Stevens (Florida Sta. Rpt. 1916, pp. 66-79, figs. 2).—The investigations reported by the author have been continued along about the same lines as previously.

A number of citrus trees which had been treated for gummosis have been kept under observation for three years (E. S. R., 33, p. 55), and many of the active areas have healed following the treatment. A study is being made of the fungus and bacterial flora associated with gummosis and several organisms are under observation, among them *Phomopsis citri* and *Diplodia natalensis*, to determine whether these fungi are active agents in producing the disease.

Pruning experiments for the control of melanose have been continued with some success, summer pruning giving very good results in reducing the amount of injury.

The author is continuing his investigations on citrus canker, paying particular attention to laboratory studies of the organism, especially in relation to soils. Pseudomonas citri has been cultured in sterilized soil for more than a year, and experiments have demonstrated that it grows readily on sterilized soil under moist conditions. Soil cultures made in the spring of 1915 have been kept under observation and in nearly every instance the organism has been found present. The infected soil has been applied to healthy citrus foliage and in all cases canker infections have resulted. Tests have been made of field soil collected under infected trees, and while in a majority of the tests there were negative results, in a few instances the presence of the organism was established by inoculation experiments.

Brief descriptions are given of lightning injury to citrus trees, the lemon brown rot fungus, citrus scab, withertip, and stem end rot. In connection with the investigation of the lemon brown rot fungus, the author reports having isolated from gumming citrus trees an organism which, when inoculated upon healthy lemons, developed a brown rot similar to that produced by *Pythiacystis citrophthora*.

The origin and cause of citrus canker in South Africa, ETHEL M. DOIDGE (Union So. Africa Dept. Agr., Sci. Bul. 8 (1916), pp. 20, pls. 10, figs. 3; ditto, Div. Bot. [Pub.] 20 (1916), pp. 8, pls. 6).—Citrus canker, claimed by Hasse (E. S. R., 33, p. 149) to be caused by an organism described by her as Pseudomonas citri, but designated by the present author as Bacterium citri, is said to have been imported on grapefruit trees from Florida. A brief history of the disease in Africa and elsewhere is given, with an account of study by the author.

At first the trouble was taken to be a severe outbreak of scab (Cladosporium citri). Serious effects may be produced even in the nursery. The organism works in buds, leaves, fruits, and branches. Orange, lime, and related plants are attacked. It is claimed that under the dry conditions of the Transvaal the disease has been effectively controlled with a 4:4:50 Bordeaux spray. This should be used two or three times the first year with a single spraying every year or two thereafter. Badly infected stock should be burnt and old cankers should be searched for, as infection may occur after four years of apparent freedom from canker.

Anaberoga, M. K. Venkata Rao (Mysore Agr. Calendar, 1917, pp. 26, 27, 30, fig. 1).—Anaberoga of the areca palm in parts of Mysore is described in connection with the fungus locally known as "anabe," which attacks trees, usually over 10 years of age, at the roots and collar and apparently spreads through the soil and by air-borne spores. Other plants of different genera, and even different orders, are also attacked by the fungus, which causes the same general symptoms, ending in the death of the tree. No remedial measures are effective after the tree is attacked.

Diseases and pests of the mango, K. Kunhikannan and C. Noronha (Mysore Agr. Calendar, 1917, pp. 7, 10, 11, figs. 3).—Failure of mango trees in Mysore to set fruits has been shown by recent observations to be due to a fungus which attacks young leaves and flower spikes. It develops most rapidly under moist conditions, the drying up of the flowers following a succession of misty or damp nights. This fungus is distinguished from other local mildews which attack tobacco and roses. Bordeaux mixture applied to the young leaves and flower spikes just before the blooms open controls the disease. A combined treatment is being sought for both fungi and troublesome insects, some of which are mentioned in this article.

**Powdery** mildew of dwarf magnolias, M. Turconi (*Riv. Patol. Veg.*, 7 (1915), No. 6, pp. 164-167).—The disease produced by species of Erysiphe on several plants is said to be associated in the case of Magnolia pumila with a fungus, the characters of which, as described, are considered to agree with those of E. polygoni.

Black canker of chestnut, B. Peyronel (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), II, No. 11, pp. 459-461).—This is a preliminary discussion of a study of black canker of chestnut, now becoming important in Italy, its manifestations, the causal or contributing agents (such as atmospheric conditions), and various related problems, such as the mode of penetration by the fungi, no trace of which appears outwardly in the early stages of the disease.

Black canker of chestnut, L. Petri (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), II, No. 5, pp. 172-176, figs. 2).—Previous reports on black canker of chestnut (E. S. R., 33, p. 854; 35, p. 250) are continued.

The author states that whether near the basal portions of the larger roots or at the collar and above that region, necrosis of the cortical tissue is a phenomenon secondary to the death of the cambium. The former portion showed at first no microorganisms, but these could be demonstrated by means of the microscope and sometimes by means of culture methods in the cambium, sapwood, and heartwood. It appears that the rapidly progressing primary infection is independent of the deeper fungi, which are probably secondary. The infection, which proceeds up the trunk, appears to have its origin at the collar.

The primary infection in black canker of chestnut, L. Petrei (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), II, No. 12, pp. 499-501, figs. 2).—More recent study by improved methods confirms the observations above noted regarding the phases or stages of black canker of chestnut. The attack originates near the junction of the roots and trunk. The identity of the primarily causal fungus remains unknown.

Leaf cast in horse chestnut, L. Montemartini (Riv. Patol. Veg., 7 (1915), No. 8-9, pp. 243-248).—This is a discussion of the factors involved in the early shedding of leaves by horse chestnut, including foliar surface and branching as related to transpiration surface and conduction. The author states that the number of conducting elements is the same as that of actively transpiring elements, both increasing in number with the amount of branching.

A needle blight of Douglas fir, J. R. Weie (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 2, pp. 99-104, pl. 1, figs. 3).—A description is given of a serious disease of Douglas fir which is causing damage to young trees and seedlings in the Northwest both in the nursery and the forest. A study of the disease indicates that it is due to a fungus, the systematic position of which has not been definitely determined.

Some preliminary experiments in spraying with a solution of soap and Bordeaux mixture give indications that this will prove a successful means of controlling the fungus.

[White pine blister rust in Canada], H. T. Güssow (Canad. Forestry Jour., 13 (1917), No. 1, pp. 900-906, figs. 6).—In this article, which has been issued also in pamphlet form, a brief popular account is given of the importation of the American 5-leaved pine (Pinus strobus) into Europe, its attack there by the blister rust fungus, the importation of the latter into America on seedlings, and the spread of the disease to such an extent that this pine and all the interests connected with it are seriously threatened. A plea is made for concerted action looking to the control of this disease. Eradication of all currant and gooseberry plants in the neighborhood of the pines is the remedy which is offered with most confidence.

White pine blister rust on currants, W. A. McCubbin (Canad. Hort., 40 (1917), No. 2, p. 34, fig. 1).—Certain features observed in the Ontario outbreak of white pine blister rust suggest that the fungus may overwinter on currant bushes. Besides the large area on the Niagara Peninsula previously known to be infected, the disease occurred, so far as known, only in small isolated patches in Ontario in localities which are named. The disease has also been reported from Quebec. The appearance and behavior of the disease on both white pine and currant are briefly described.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

A check list of mammals of the North American continent, the West Indies, and the neighboring seas, D. G. Elliot (Pubs. Field Columb. Mus. [Chicago], Zool. Ser., 6 (1905), pp. V+761, pl. 1; Sup., New York: Amer. Mus. Nat. Hist., 1917, pp. IV+192).—The check list proper is supposed to include all

the species and races of mammals, described up to the date of publication, which inhabit the North American continent from the Arctic Ocean to the Province of Cauca in Colombia, South America, together with those of the West Indies Islands and the adjoining seas. They are arranged systematically according to the author's views, and descriptions are given of those forms that have received names since his two previous works were published 1 (E. S. R., 16, p. 233). The species enumerated in the list number 1,309 and 676 races of species found within the geographical limits embraced, together with 22 races of exotic species originating in South America. The type locality and geographical distribution, where known, are given in every instance.

The supplement, which is edited by J. A. Allen, lists the species and subspecies that have for the most part been described since the publication of the earlier works on which the check list was based, down to the end of the year 1914. In addition to being a supplement to the check list, it is also a continuation of the preceding two manuals on the subject, since it gives descriptions of forms added as well as the usual check list matter. It contains many changes in generic nomenclature from that of the check list proper, many groups treated in the latter as subgenera being given the rank of genera, while the changes in generic names shown to be necessary since the publication of the check list are duly recorded.

Report of the entomologist, J. R. Watson (Florida Sta. Rpt. 1916, pp. 51-65).—Attempts to establish Calosoma sycophanta were not successful and it appears that this beetle is not adapted to the climatic conditions of Florida.

In further observations (E. S. R., 35, p. 852) of the Florida flower thrips ([Euthrips] Frankliniella tritici projectus) kept in test tubes constantly supplied with fresh rose petals, many lived for several weeks, and one individual lived for 59 days. The observations establish the fact that they spend the winter as adults, though there may be some breeding during the warm periods in any month of the year, but there are no indications that they ever enter the ground or seek other shelter than the depths of the flowers. The author's observations show that prolonged and dashing rain is the chief natural factor in reducing the numbers of thrips. Spraying work in the control of thrips on citrus indicates that it will pay well for one spraying even when the bloom is unusually irregular and scattering.

Studies made of an outbreak of thrips on strawberries at Waldo showed the infestation to be heavy, as many as 50 adults and larvæ being found in a single bloom. When thus heavily infested the bloom failed to set fruit. Successful control of the pest was obtained through the application of a home-made tobacco decoction of tobacco stems soaked overnight in enough water to cover them, applied at the rate of 3 gal., and a pound of soap to each 15 gal. of water.

In April, 1916, the Florida flower thrips was found to injure camphor trees, the damage to the unfolding buds of camphor being very similar to that caused by the camphor thrips, previously noted (E. S. R., 31, p. 751).

Work on combating nematodes by the use of calcium cyanamid is noted on page 652.

The report concludes with brief notes on the insects of the year, including accounts of an unusual outbreak of the striped cucumber beetle in south Florida, where they killed bearing okra plants and watermelons and even attacked Irish potatoes, and destroyed the young growth of citrus, it being the first record of injuries to citrus in Florida by this pest. The woolly white fly (Aleurothrizus howardi) continued to extend slowly into the regions adjacent to its previous range. The cowpea pod weevil (Chalcodermus aeneus) is said to have

<sup>&</sup>lt;sup>1</sup> Synopsis of North American Mammals. (Field Columbian Mus., Zool. Ser., 2 (1901).

been more abundant than usual during the spring of 1916, it being especially so on the California black-eyed variety of cowpeas. A June bug (Anomala marginata) was especially abundant in June. The twig girdler (Oncideres cingulatus) was the cause of several complaints from the lower east coast where it attacked "Australian pines."

Undesirable insect immigration into New Jersey, H. B. Weiss (Canad. Ent., 49 (1917), No. 9, pp. 293-298, pl. 1).—The author calls attention to the fact that fully one-half of the principal injurious hexapods in the United States have been introduced from foreign countries and that the injuries inflicted by them have been enormous. Mention is made of the introduction into New Jersey of the mole cricket Gryllotalpa gryllotalpa from Holland (E. S. R., 34, p. 653), the large cockroach Blaberus discoidalis from South America (E. S. R., 37, p. 255), Stephanitis pyrioides from Japan, and Cholus forbesis from Colombia.

Fumigation of greenhouses, E. N. Cory (Maryland Sta. Bul. 205 (1917), pp. 263-284).—This bulletin is based upon fumigation experiments conducted with the view of ascertaining the effect of certain doses of hydrocyanic-acid gas on insects and plants when certain factors are known, including moisture and temperature, meteorological conditions, time (day or night), and length of exposure. The investigations were largely limited to the determination of effective dosage for certain insects under normal conditions, but little work having been done with one factor constant and others variable in order to ascertain the effect of the variables, which, it is pointed out, is a very important phase of fumigation.

The conclusions drawn from the work carried on are as follows: "Fumigation in the presence of daylight is likely to result in injury to the plants if a sufficient dose is used to control the ordinary insects. . . . Overnight fumigation is recommended because (1) fumigation in late afternoon for a short period is impractical in winter, since ventilation after nightfall is likely to result in chilled or frozen plants; (2) long exposure at night does not give as much injury as a short exposure during the day.

"Definite doses under optimum conditions of moisture and temperature for different horticultural varieties of plants can be recommended. Definite doses, under the normal greenhouse conditions, that will kill certain species of insects are recommended. Slight reductions in the doses may be effected by increasing the temperature up to a maximum of 70° F. without danger of injury to the plants if the moisture is kept at or below 50 per cent saturation. High moisture is decidedly an important factor as far as injury to the plant is concerned. High moisture will increase the mortality if the dose is below the optimum for the insect involved.

"High temperature will increase the mortality if the dose is below the optimum for the insect involved. Plants that are normally grown under warm conditions, such as 'stove plants,' will not be injured by fumigations in a temperature that would injure bedding plants and plants grown for cut flowers. Plants other than 'stove plants' should be fumigated if possible with the optimum dose for the insect involved, at a night temperature at or below 50° and with the atmosphere about half saturated."

In an appended table the author gives the maximum safe dose for various plants under normal greenhouse conditions.

A neglected factor in the use of nicotin sulphate as a spray, W. Moore and S. A. Geaham (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 1, pp. 47-50).—Illness caused by the consumption of greenhouse lettuce that had been sprayed with nicotin sulphate led to the studies at the Minnesota Experiment Station here reported.

The results show that nicotin sulphate is nonvolatile, but that alkalies contained in hard water and soap set free the nicotin contained in nicotin sulphate sprays. Thus, in order to obtain the maximum efficiency of tobacco extracts containing nicotin sulphates, they should be rendered alkaline before using. This is thought to explain the different results obtained in the use of tobacco extracts, and also why soap greatly increases the efficiency of sprays containing nicotin sulphate. The fact that nicotin sulphate is nonvolatile also explains the cases of poisoning from eating lettuce sprayed with tobacco extracts containing this material.

"Commercial tobacco extracts containing nicotin sulphate should not be used in the greenhouse, at least not on plants which are later to be used for food. Tobacco extracts or tobacco papers containing free nicotin may safely be used in the greenhouse on plants such as lettuce without endangering the lives of the consumers. Food plants such as lettuce sprayed with tobacco extracts containing free nicotin should not be cut for the market until the day after spraying. If the temperature of the house is low, a longer period should be given the nicotin to evaporate from the leaves."

Grasshopper control, C. R. Jones (Colorado Sta. Bul. 233 (1917), pp. 3-29, figs. 17).—A summary of information on the general life history, habits, and practical methods of control of grasshoppers, based upon work in Colorado during the outbreaks of 1916. The subject is taken up under the headings of life history; food habits—the plants affected; natural and artificial control; apparatus for capturing grasshoppers, including the hopperdozer, balloon catcher, and the live hopper machine; insecticides; diseases; etc. The bulletin concludes with a discussion of the work during 1916.

A further contribution to the study of Eriosoma pyricola, the woolly pear aphis, A. C. Baker and W. M. Davidson (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 2, pp. 65-74, pls. 2, fig. 1).—In the present paper, which gives the complete life of cycle of E. pyricola, the authors first discuss the history of the different species of plant lice recorded on pear roots (Pyrus communis) at some length. The species Prociphilus pyri (Fitch) has been found to be a homonym and the name P. fltchii is proposed for it. It is shown to be definitely established that the European pear-root aphis (E. pyri Goethe), described in 1884, is the alternate form of the elm species E. lanuginosa (Hartig) of 1841.

In a paper previously noted (E. S. R., 35, p. 463) the authors described the American woolly pear aphis, previously thought to be the woolly apple aphis, under the name *E. pyricola* and called attention to its close resemblance in general structure to European specimens of *E. lanuginosa*. Studies since conducted have shown that the marked difference in the wax pores and minor differences in the sensoria then considered as representing a very distinct species are not the same in the spring forms living on elms as in the summer and fall forms living on pear roots, those in the spring forms being very similar to those of *E. lanuginosa*. The very great similarity between the spring forms of *E. pyricola* and *E. lanuginosa* has led the authors to believe that the same variation will be found between the spring and fall forms of *E. lanuginosa*, which if it proves true—and it is regarded as all but proved—will result in *E. pyricola* becoming a synonym of *E. lanuginosa*.

Thus it would appear that "the destructive woolly pear aphis of this country is a European insect imported into the Western States on pear stock. It has spread rapidly in the West in the last 25 years and now occurs from Washington to California, although as yet it is most destructively abundant in California. The isolated infestations in the Middle West and in the East are due to separate infested importations. While the alternate winter forms thrive best on European elms, the species is able to live successfully upon the common American

elm and at no very distant date may become entirely adapted to this native tree. The species is liable through importations to gain a foothold in any peargrowing region, for, as recently as 1916, skins have been collected on seedling nursery stock. . . .

"The fall sexuparous migrants leave the pear roots upon which they have developed and fly to elm trees to deposit the sexes on the trunks and limbs. These migrants settle on *Ulmus americana* and *U. campestris*. The latter tree is distinctly preferred; in fact, no perfect galls have been produced on the former. The sexed female after mating deposits a single egg in a crack in the bark or underneath a bud scale. . . . From this egg hatches the young stem mother which ascends a trunk or limb and seeks an expanding leaf. In 1916 hatching commenced March 23 and extended until April 18, the majority hatching during the first two weeks of April."

The newly-hatched stem mother settles on the underside of the elm leaf near the midrib, generally not far from the base. "After the young aphid has fed for a very few days, the leaf begins to curl around it, and the curling and twisting become more pronounced as the insect grows, so that by the time it has reached the third instar the leaf in the form of a gall has completely closed around it." Following upon the maturing of the stem mother the galls grow very rapidly and change their shape. "The possibility of the second generation's wingless forms leaving the parent gall and founding new galls should not be overlooked; yet the observations made indicate either that no such movement exists or that it is uncommon."

In 1916 nearly every gall examined contained winged forms by the fourth week in June, large numbers of the earlier galls had been vacated by July 10, and by the end of July hardly a gall with living inmates could be found. Spring migrants were observed resting on pear foliage and actively crawling up and down the lower part of the pear trunks, young deposited by them were taken in spider webs at the base of pear trees, and it appears that the young are normally deposited on pear trunks at or near to the soil surface. Spring migrants when placed in Petri dishes with pieces of pear roots on wet sand deposited young which readily settled and fed upon the roots and which precisely resembled in structure the newly-born larvæ of the pear-root aphis. The young deposited by the spring migrants readily fed on pear stocks of Kieffer, French, and Japanese varieties, but like the root-dwelling larvæ absolutely refused to feed upon apple roots and fed only in very rare instances upon roots of the quince.

The life history account is accompanied by a diagram of the complete life cycle of the species. A list of ten titles cited is appended.

The aphid of tea, coffee, and cacao (Toxoptera coffee), F. V. Theobald (Bul. Ent. Research, 7 (1917), No. 4, pp. 337-342, figs. 3).—A summarized account of T. coffee.

Observations on Lecanium corni Bouche and Physokermes picese Schr., F. A. Fenton (Canad. Ent., 49 (1917), No. 9, pp. 309-320, pl. 1, figs. 13).—A report of biological studies of the European fruit lecanium (L. corni) and the spruce scale (P. picese) at Madison, Wis.

L. corni, observations of which in New York by Slingerland (E. S. R., 6, p. 1004) and by Lowe (E. S. R., 9, p. 71) have been noted, now occurs throughout most of the United States. It has a wide variety of host plants, a list here given including 36 genera, representing 21 families. In spite of the wide range of its host plants and its general distribution this insect seldom becomes of economic importance, although serious outbreaks of it have been recorded, it having occurred in New York in destructive abundance on the plum and in

California on apricots and prunes. Successful transference to different host plants is recorded.

Several parasites have been reared in Michigan from *L. corni*, which on some trees was so badly parasitized as to be almost exterminated. In the vicinity of Madison, Wis., *Coccophagus lecanii* was by far the most numerous and effective, though in California *Comys fusca* appears to be the chief check. Several insect predators are mentioned and the adult females are said to be susceptible to several fungus diseases, of which that caused by *Cordyceps clavulatum* is the most important.

The spruce scale, a European pest first discovered in this country at Hartford, Conn., in 1906, and since found in various northern localities as far west as Wisconsin has become a serious pest. It appears to be dependent upon spruce and pine for host plants, preferring the Norway spruce (*Picea abies*). A parasite representing a new species, described by Girault as *Holcencyrtus physokermis* (E. S. R., 36, p. 555), which appears to have been introduced with *P. piceæ* from Europe, is effective in checking its spread. *Cheiloneurus albicornis* and several encyrtids were also reared from this scale.

Pupæ of some Maine species of Notodontoidea, Edna Mosher (Maine Sta. Bul. 259 (1917), pp. 29-84, figs. 5).—The importance of being able to recognize insect pests in any stage of their life cycle led to studies of the pupæ of some of the more common forms of notodontid moths found in Maine, a report of which is here presented. Twenty-eight species representing 21 genera are thus dealt with.

Life history of Plutella maculipennis, the diamond-back moth, H. O. Marsh (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 1, pp. 1-10, pls. 2).—This report, based largely upon studies made since 1908 at Rocky Ford, Colo., includes observations at Phoenix, Ariz.

P. maculipennis is a cosmopolitan species which in the United States apparently occurs wherever cabbage is grown. It feeds exclusively on cruciferous plants, having been observed by the author to feed upon cabbage, cauliflower, turnip, radish, rape, kale, mustard, Chinese mustard, kohl-rabi, water cress, horse-radish, sweet alyssum, and candytuft, and also on two weeds, wild watercress (Roripa sinuata) and hedge mustard (Sisymbrium sp.). While cabbage is decidedly the favorite, rape, cauliflower, turnip, and mustard are readily eaten.

Seven generations occur annually at Rocky Ford, where the winter is passed as an adult. The egg stage covered from 3 to 6 days, the larva stage from 9 to 28 days, and the pupa stage from 5 to 13 days. In the South the diamond-back moth is active throughout the year, and the larvæ are to be found at all seasons. The larvæ reared at Rocky Ford during May lived as leaf miners for the first two or three days of their existence, whereas those reared at Phoenix during February lived in mines for four days.

While potentially a serious pest, it is normally held in suppression by parasites, of which the most effective is an ichneumonid, Angitia plutellæ, which in turn is occasionally parasitized by Spilochalcis delira. From 50 to 70 per cent of the larvæ of later generations of the diamond-back moth are commonly found parasitized by A. plutellæ. Other parasites reared by the author proved to be Meteorus sp., Mesochorus sp., and a new species of Microplitis. No. parasites of the eggs or pupæ and no predacious or fungus enemies have been observed. It is readily controlled by the use of arsenicals, of which Paris green 2 lbs. and soap 6 lbs. to 100 gals. of water is the most effective. Powdered arsenate of lead at the rate of 4 lbs. in 100 gal. of water is also effective.

The tobacco budworm and its control in the southern tobacco districts, A. C. Morgan and F. L. McDonough (U. S. Dept. Agr., Farmers' Bul. 819

(1917), pp. 11, figs. 2).—This lepidopteran (Chloridea virescens) is a very serious pest in the tobacco-growing sections of Florida, Georgia, Alabama, and Louisiana. Although common in North Carolina, South Carolina, and Virginia, it is much less injurious there than in the more southern part of its range and is rarely injurious in Kentucky and Tennessee. In addition to tobacco, the species has been recorded in the United States as attacking deer grass (Rhexia virginica), geranium, and ageratum, and has been reported to feed upon wild solanaceous plants, including ground cherry (Physalis viscosa) and other species of the same genus, and Solanum seiglinge.

Eggs are deposited singly on the leaves and in Florida during the growing season of tobacco hatch in from 3 to 5 days. The young larvæ migrate to and reach the buds in about 24 hours. Studies have shown the larval period to cover from 18 to 31 days during May and June, the pupal stage varying during the summer from 13 to 21 days. The emergence of adults from the ground is affected materially by moisture conditions, it having been observed that a great many moths often appear at the expiration of a dry period. In captivity moths laid an average of 334 eggs. The average duration of the life cycle during May and June, 1916, was determined to be 37.5 days.

A larval parasite (Toxoneuron sp.) is said to be its most important enemy. In control work 30 different insecticide formulas were tested during the seasons from 1913 to 1916. Of all the poisons used Paris green, arsenate of lead, and golden antimony sulphid applied directly to the bud with corn meal as a carrier gave the most promising results, there being, however, a great variation in the efficiency and cost in their application. A mixture of 1 lb. of arsenate of lead and 75 lbs. of corn meal has proved to be the most efficient combination, the loss from burning which follows the use of Paris green thus being eliminated. For the best results the buds must be treated twice a week until topping has been completed. Other supplementary control measures recommended include the removal from the field and destruction of suckers, 55 per cent of those removed having been found to be infested; the removal at the end of the season of the tobacco plants that remain standing in the fields; patching of holes in the cheesecloth and gates kept closed where tobacco is grown under cloth; destruction of plants left growing within and around old seed beds; and the covering and walling in of seed beds with cloth so as to prevent the entrance of moths.

Some recent advances in knowledge of the natural history and the control of mosquitoes, T. J. Headle (New Jersey Stas. Bul. 306 (1916), pp. 5-26, figs. 10).—Reference is first made to the influence of salinity on the development of certain species of mosquito larve, an account of studies of which by Chidester has been noted (E. S. R., 37, p. 259). Studies in the laboratory and salt marsh have shown "that highly saline water (10 to 15 per cent) is favorable to the growth of the wrigglers of the white-banded salt-marsh mosquito (Aedes sollicitans) and injurious (deadly if sufficiently high) to the wrigglers of the brown salt-marsh mosquito (A. cantator), while only slightly salt water (6 to 8 per cent) is favorable to the latter and injurious to the former. The younger the larve the more acutely are they affected by the degree of salinity."

A method of rapidly tracing the migrating mosquitoes to their origin by use of an automobile, starting in uninfested territory close to the infested area and collecting at regular distances, 0.5 to 2 miles, until the mosquito zone had been traversed and uninfested country found on the other side, resulted in the discovery of the breeding places of many broods. This method is illustrated by a diagram. It was clearly shown in one case by collections between 8 and 9.30 p. m. that Culex pipiens migrated a distance of 2.5 miles from its

place of breeding, though as a matter of fact much study of this species on the wing indicates that except when bred in enormous numbers over many acres of sewage-charged water, the areas of great density are small and isolated from each other, showing clearly that slight, if any, migration, has taken place.

**Drainage** and the elimination of mosquito breeding areas are considered at some length under the headings of upland drainage, salt-marsh drainage, diking and tide-gating, and pumping.

The work with larvicides has seemed to indicate that fuel oil is the best for general use. Tests of sulphuric acid indicate that it can not have any great importance as a larvicide, while work with chlorin (bleaching powder) seems to show that it can not have more than a limited use. Electrolytic tests made of a machine consisting of a gasoline-engine-driven dynamo, connecting wires, and electrodes, in a meadow near Grasselli gave no evidence of their destruction of mosquito larvæ. In a test of niter cake it was found that the pupæ survived in a saturated solution.

The domestic flies of New Jersey, C. H. RICHARDSON (New Jersey Stas. Bul. 307 (1917), pp. 5-28, flgs. 18).—A summary of information on the more important domestic flies, based upon studies conducted for the past three years at the station, the results of which have been previously noted (E. S. R., 32, pp. 60, 550; 34, p. 160; 36, p. 156).

The species concerned are the house fly, flesh flies, blow flies and allied species, the stable fly (Muscina stabulans), the little house fly (Fannia canicularis), the cluster fly (Pollenia rudis), etc. A summary of information on the breeding places of domestic flies, their eradication, a key to the common domestic flies of New Jersey, and a bibliography of 20 titles are included.

Some fly poisons for outdoor and hospital use, A. C. Jackson and H. M. Lefroy (Bul. Ent. Research, 7 (1917), No. 4, pp. 327-335).—"The fluorids, iodates, and salicylates are all excellent for indoor purposes and used at 1 per cent in sugar solution are not in any way dangerous or offensive. Formaldehyde is so uncertain that its use is not indicated when any other safe liquid can be employed; the reasons for the variability of its action are now under investigation. For hospital use, particularly, the very small quantity needed makes even the salicylates possible as useful fly poisons; an ounce of salicylate to 5 pints of water would poison flies for some time throughout quite a large hospital, and this amount could probably be spared. The fluorids are in use as indoor fly poisons in the Imperial College, where they successfully destroy flies that escape to the laboratories from the fly rooms."

The apple maggot in British Columbia, R. C. TREHEBNE (Canad. Ent., 49 (1917), No. 10, pp. 329, 330).—The author records the collection at Penticton, B. C., on July 26, 1916, of two adult flies of the apple maggot. This is said to be the first record of its collection in the Province of British Columbia and is practically an original record for the Pacific coast of North America.

The dipterous families Sepsidæ and Piophilidæ, A. L. MELANDER and A. SPULER (Washington Sta. Bul. 143 (1917), pp. 3-103, figs. 28).—In the present bulletin the authors deal with the flies commonly combined as the family Sepsidæ. These are of economic importance as they are principally scavengers, feeding and breeding in filth, sewage, excrement, carrion, and other decomposing vegetable or animal matter. A synopsis of the Sepsidæ is first presented (pp. 6-53), followed by a synopsis of the Piophilidæ. The authors recognize 51 species belonging to 18 genera, of which 19 are described as new.

A catalogue of described species is included.

Notes on some Buprestidæ of northern California, W. J. CHAMBERLIN (Ent. News, 28 (1917), Nos. 3, pp. 129-139, flys. 10; 4, pp. 166-169).—These notes, which relate to 61 species, include data on their occurrence and hosts.

Biological investigation of Sphenophorus callosus, Z. P. METCALF (North Carolina Sta. Tech. Bul. 13 (1917), pp. 5-123, pl. 1, figs. 68).—Investigations of the southern corn bill bug commenced by the author in the spring of 1912 and carried on until the fall of 1915 are reported in connection with the earlier work by Smith, as previously noted (E. S. R., 29, p. 56). The biologic and economic aspects of the investigation are dealt with, other phases of the problem being left for a later report. Much of the data is presented in tabular form.

Observations of its biology made in the southwestern part of the State, thought to apply throughout the area of its greatest abundance in North Carolina, have been summarized as follows: "The adults hibernate over winter, going into hibernation in late October (October 17 being the latest recorded date). They emerge from hibernation in mid-April (April 10 being the earliest date recorded). Their numbers seem to increase rather rapidly until late May, and after that rather slowly until mid-August. . . . After mid-August the numbers of adults diminish rapidly, so that in early corn practically all the adults have disappeared by the end of August. A few adults remain active to late October.

"The adults commence to lay eggs by early May (May 5 being the earliest recorded date). The number of eggs found in the field increases rather rapidly until mid-June and then less rapidly until mid-July, the number of eggs falling off slightly toward mid-August. After this the number decreases rather rapidly. The latest date recorded for finding eggs in the field is September 23, but as they were still rather common at that time, it seems safe to conclude that egg laying continues until early October, especially as the adults are active in the fields till late October.

"The distribution of the larvæ throughout the year seems to coincide rather closely with the distribution of the eggs. The earliest larvæ have been found in the field in mid-May, but the time of greatest abundance seems to be from late July to mid-August. After this time their numbers fall off rapidly, the latest larvæ being found in late October (larvæ in what appeared to be the fourth molt being found on October 27).

"The earliest pupe have been found in late June. The number increases rather rapidly till late July and seems to remain nearly constant till late September, the latest pupa being found on November 9. These late-maturing pupe seem to all change to adults before winter, and these adults seem to remain in the pupal cells over winter, not becoming active until the following spring. There is some evidence to show that the early maturing adults lay eggs the same summer that they reach maturity, these eggs hatching and reaching maturity late in the season."

The following are thought to be the most important factors involved in any system for the control of this pest, both from the standpoint of ease and cheapness of application: (1) Time of planting, (2) rotation of crops, (3) fertilization, (4) drainage, (5) ridging, (6) fall and winter plowing, (7) thorough cultivation, and (8) destruction of native food plants. These indirect measures are the only means of control, since the habits of the pest make it impossible to apply direct measures.

A bibliography of 17 titles is included.

An annotated list of the scolytid beetles of Oregon, W. J. CHAMBERLIN (Canad. Ent., 49 (1917), Nos. 9, pp. 321-328; 10, pp. 353-356).—This list includes descriptions of seven new species.

Destruction of wheat by wasps, F. W. Feblawk (Entomologist, 50 (1917), No. 649, pp. 132, 133, fig. 1).—Vespa vulgaris, a common wasp in England, is said to feed upon and damage the heads of wheat in that country.

The host of Ablerus clisiocampæ, B. A. PORTER (Ent. News, 28 (1917), No. 4, p. 186).—The author records the rearing of A. clisiocampæ in some numbers from the egg masses of the tent caterpillar, together with Telenomus coloradensis, Tetrastichus malacosomæ, and Ooencyrtus sp., of which T. malacosomæ was by far the most abundant.

A new West Indian chalcid fly, A. A. GIRAULT (Canad. Ent., 49 (1917), No. 10, pp. 356, 357).—Achrysocharella albitibiæ n. sp. is described from a single female collected in St. Vincent.

Notes on Perisierola emigrata, a parasite of the pink bollworm, A. Busck (Insecutor Inscitiæ Menstruus, 5 (1917), No. 1-3, pp. 3-5).—These notes relate to observations in Hawaii of the species described as new and previously referred to as Goniozus cellularis, the larva of which is an external parasite of the full-grown pink bollworm. It was found to occur commonly in all the cotton fields on the island of Oahu and in the Kona cotton district of Hawaii, and is at present the only parasite of the pink bollworm of any importance. It is, however, by no means an effective check, and destroys only a small percentage of the cotton pest.

Notes on coccid-infesting Chalcidoidea, III, J. WATERSTON (Bul. Ent. Research, 7 (1917), No. 4, pp. 311-325, figs. 7).—This continuation of the article previously noted (E. S. R., 37, p. 467) includes descriptions of three new species and one new variety from the West Coast of Africa.

Two new species of Macrophya, S. A. Rohwer (Ent. News, 28 (1917), No. 6, pp. 264-266).

The occurrence of the genus Monobæus in North America, A. A. GIRAULT (Ent. News, 28 (1917), No. 3, p. 106).—A new species, Monobæus hegeli, is described from a female specimen from Michigan.

Notes on some parasites of sugar cane insects in Java, with descriptions of new Hymenoptera Chalcidoidea, A. A. Girault (Entomologist, 50 (1917), No. 649, pp. 134-136).—Three parasites, probably of economic importance, are here described as new, namely, Gonatocerus bifasciativentris reared from eggs of a leafhopper embedded in the leaves of sugar cane; Parachrysocharis javensis, n. g. and n. sp., from Flata affinis; and Cyrtogaster javensis, from lepidopterous eggs.

The hothouse milliped, E. N. Cory and F. H. O'Neill (Maryland Sta. Bul. 206 (1917), pp. 283-294, figs. 3).—Reports received at various times attributing injuries to the hothouse milliped (Oxidus gracilis) and requests by florists and gardeners for information regarding its economic status led to the hothouse studies here reported.

This myriapod, a species of tropical origin widely distributed in temperate climates, is thought to have been introduced into the United States from Europe. Its distribution in this country seems to include the States along the Atlantic coast and as far west as the Mississippi Valley.

It is rarely seen during the day, being nocturnal in its habits. There appears to be but one generation a year, although the date of the oviposition period varies so much with individuals that specimens of all sizes may be found at almost any time.

The eggs are usually laid in the spring in masses, those counted containing from 9 to 327 eggs, and the average cluster containing from 175 to 250 eggs. The first eggs were observed on February 9, although the greatest number were found during April and May. The depth to which they are placed in the soil

varies with its nature and not in any special cavities in the soil or apparently with any relation to the proximity of food. In packed clay soil the depth to which the eggs were deposited varied from 0.5 to 1 in. below the surface, and in light sandy soil the average depth was from 1.5 to 2 in., although some few clusters were found as deep as 3 or even 4 in. below the surface. The eggs hatched in 20 days at a greenhouse temperature ranging from 58 to 76° F.

Five larval stages are described. The first stage has 5 pairs of legs and the succeeding larval stages 10, 29, 31, and 35 pairs, respectively. Roomy cells are formed in the earth in which they pass the molts.

Observations show that manure or decaying vegetable matter is the principal food of these millipeds. Experimental feedings indicate that they will not burrow in sand after the raw ends of cuttings or the newly formed roots, that they will not attack the stems of plants even under the stress of hunger, and that they can subsist for some time on the humus in the soil. The millipeds occasionally attack sprouting seeds, and it is believed that they can be starved into attacking the roots of some plants and under certain conditions may damage them to a limited extent.

The green alga that grows on moist flower pots appears to be an important source of food for this species. Observations indicate that it has predactous habits also, a half-grown milliped having been observed to attack and destroy a dipterous larva that was about 3 mm. long, and it was also observed to feed upon the remains of an earthworm, a green aphid, etc.

No parasites have been reared up to the present time but a small centiped is thought to attack it. In control work the authors' experiments with poison baits gave negative results, although they have been recommended as being efficient in some localities. Tests of tobacco products show that they are probably the best material for the control of the hothouse milliped. Tobacco dust sprinkled on the beds at the rate of 300 lbs. to the acre (1 oz. to 9 sq. ft.) has proved fairly effective, about 85 per cent of the millipeds on the beds being found dead the following day, although some apparently normal individuals were moving around through the dust, and only about 5 per cent of the millipeds below the surface were dead. Forty per cent nicotin sulphate was applied with good results at strengths varying from 1 part to 750 parts of water to 1 part to 1,000 parts of water. When applied at the weaker strength with a watering can until the soil of the beds was thoroughly drenched about 90 per cent were killed by the treatment, including nearly every milliped within 3 in. of the surface.

## FOODS-HUMAN NUTRITION.

How to select foods.—II, Cereal foods, CAROLINE L. HUNT and HELEN W. ATWATER (U. S. Dept. Agr., Farmers' Bul. 817 (1917), pp. 23, figs. 5).—Continuing previous work (E. S. R., 37, p. 364), this publication deals with foods rich in starch and especially with the cereals and foods made from them.

Cereals, it is pointed out, are mild-flavored and comparatively inexpensive foods, which are very largely depended upon to yield energy to the body. In addition to this, they also yield varying but important amounts of tissue-building and body-regulating substances. Rightly combined with well-chosen food materials from other food groups, cereals can be safely used as the main part of the ration. Wisely planned, a diet in which cereals are so used can be made adequate, attractive, and at the same time economical.

Eggs in a thousand ways, A. MEYER (Chicago: The Hotel Monthly Press, 1917, pp. 140).—A compilation of recipes for the preparation of eggs for the table.

Milk as a food (U. S. Dept. Agr., Bur. Anim. Indus. [Pub., 1917], p. 1).—A summary of data comparing milk and other foods.

How to use skim milk.—Ways in which this nutritious food material may be used to advantage in cookery (U. S. Dept. Agr., Bur. Anim. Indus. [Pub., 1917], p. 1).—A summary of popular information with recipes.

Buttermilk a food drink (U. S. Dept. Agr., Bur. Anim. Indus. [Pub.], (1917), pp. 2).—A summary of data, with recipes.

The food value of American cheese (U. S. Dept. Agr., Bur. Anim. Indus. [Pub.], (1917), pp. 2).—A popular comparison of cheese with other foods.

Ways to use cottage cheese (U. S. Dept. Agr., Bur. Anim. Indus. [Pub.], (1917), pp. 2).—Popular information and recipes.

The nutritive value of edible fungi (Jour. Bd. Agr. [London], 24 (1917), No. 4, pp. 416-419).—A discussion of data in which the general conclusion is drawn that, while fungi can not be compared with meat or ranked with the essential foods, they should not be looked upon as absolutely worthless. They may be made to serve useful purposes as food accessories because of their agreeable flavor.

Cider fruit for table use, B. T. P. BARKER (Jour. Bd. Agr. [London], 24 (1917), No. 4, pp. 394-402).—The author concludes that, under present condiditions, apples commonly used for cider should be used for cookery and the culls for jam making.

Botulism.—The danger of poisoning from vegetables canned by the coldpack method, E. C. Dickson (Jour. Amer. Med. Assoc., 69 (1917), No. 12, pp. 966-968).—The occurrence of a number of cases of botulism in the Pacific coast region led to a study of the possibility of conveying this disease by canned goods, especially those prepared by the cold-pack method. In experimental tests quart jars of peas, beans, and corn were inoculated with an emulsion containing spores of Bacillus botulinus, the jars of peas and beans being left in boiling water in a wash boiler for 120 minutes, and the jars of corn for 180 minutes. They were sealed immediately after removal from the boiler, inverted, and placed in a dark closet.

Within three weeks fermentation with the formation of gas was noted in all the jars. Some of the jars were leaking. On opening the jars a strong odor, resembling butyric acid, was noticed and cultures from all the jars showed a mixture of B. botulinus and B. subtilis.

Portions of the juice from all the jars were injected into guinea pigs and some of the canned peas were fed to a chicken. "All the guinea pigs died within 20 hours, and the chicken developed symptoms of limber-neck and died within 30 hours. A portion of the juice from the corn was passed through a diatomaceous filter and injected into a guinea pig, and the animal died within 24 hours. The symptoms of all the guinea pigs and of the chicken were identical with those produced by the toxin of the *B. botulinus* which is formed in meat broth."

The author believes that the experimental data reported prove that "the cold-pack method of canning vegetables is not efficient if the raw material happens to be contaminated with spores of the *B. botulinus*. The fact that both *B. subtilis* and *B. botulinus* were recovered in cultures from the contents of the jars proves that a single sterilization for the time recommended in the published directions is not sufficient to cause the destruction of spores. Fortunately, the number of spore-bearing bacteria which are responsible for producing poisonous changes in food is small, but the *B. botulinus* belongs to this small group, and since it is also an obligative anaerobe, the conditions which exist in the sealed jar or can are ideal for its growth and toxin formation."

In discussing the results it is also pointed out that the percentage of canned goods which would be normally infected with spores of B. botulinus would probably be small.

The practical conclusion drawn by the author is that "the botulinus toxin is easily destroyed by heating, and all danger of botulism will be removed from home-canned products if the food is always boiled before it is eaten or even tasted. Under no circumstances should home-canned vegetables which have been prepared by the cold-pack method be served as salad unless they have been cooked after their removal from the container, and, until it is established what fruits are suitable for the formation of the toxin, it will be safer to reheat all fruits which have been prepared by this method, even though there may be no apparent evidence that the food has spoiled."

Canned food safe (U. S. Dept. Agr., Weekly News Letter, 5 (1917), No. 16, p. 6).—The following statement prepared by bacteriologists of the Bureau of Chemistry and the States Relations Service has been issued:

"There is no danger that the type of food poisoning known as 'botulism' will result from eating fruits or vegetables which have been canned by any of the methods recommended by the U. S. Department of Agriculture, provided such directions have been followed carefully. It is possible that in a number of instances the directions were not strictly followed and that spoilage has occurred. Of course, extreme care should be taken to ascertain before eating canned goods of any kind whether they are in good condition, and if they have spoiled they should not be consumed.

"In case of any doubt as to whether the contents of a particular can have spoiled, the safest plan is to throw it away, although all danger of botulism may be avoided by boiling the contents of the can for a few minutes, since the Bacillus botulinus and the toxin or poison which it produces are killed by such treatment. No canned food of any kind which shows any signs of spoilage should ever be eaten. In the cold-pack method of canning given out by the Department of Agriculture, only fresh vegetables are recommended for canning, and sterilization is accomplished by the following processes: Cleansing, blanching, cold dipping, packing in clean hot jars, adding boiling water, sealing immediately, and then sterilizing the sealed jars at a minimum temperature of 212° F. for one to four hours, according to the character of the material. Since the spores of B. botulinus are killed by heating for one hour at 175° F. (according to Jordan's Bacteriology and other recognized textbooks) there is no reason to believe that the botulinus organism will survive such treatment."

Food supplies in war time, R. H. Rew (London: Oxford University Press, 1914, pp. 19).—A digest of data regarding the quantities of food available.

Utilization of food ([Columbus], Ohio: Agr. Div. Ohio Branch Council Nat. Defense, [1917], pp. 44).—This publication is prepared by the home economics department of the Ohio State University. Suggestions and recipes are given for the preparation of fresh and dried fruits, vegetables, salt fish, and cereals.

High cost of living (Washington: Govt., 1917, pp. 119).—This is a report of the minutes of a conference of the Federal Trade Commission with delegates appointed by the governors of the several States to confer regarding food and fuel supplies and prices.

Report on the increased cost of living for an unskilled laborer's family in New York City (New York: City, 1917, pp. 32).—This publication reports the results of comparative studies made in February, 1915, and February, 1917, by the Bureau of Personal Service of the Board of Estimate and Apportionment, as to the cost of living for the family of an unskilled laborer, which consisted of two adults and three children aged 6, 10, and 13 years.

A survey of evidence regarding food allowances for healthy children, Lucy H. Gillett (N. Y. Assoc. Imp. Condition Poor Pub. 115 (1917), pp. 24).—
This publication summarizes, under three headings, the evidence regarding the energy and protein requirements of children, consisting of (1) dietary studies, in which the weight of food eaten has been recorded for a given period of time and food values determined by analysis or calculated from average composition; (2) metabolism experiments, in which measurements have been made of the amount and composition of the food eaten and of the excretory products; and (3) respiration experiments in which the body heat has been estimated from the respiratory quotient.

A bibliography is appended.

The influence of diet on the heat production during mechanical work in the dog, G. Lusk (Proc. Soc. Expt. Biol. and Med., 14 (1917), No. 5, pp. 92, 93).—The data here reported show that "when a dog runs at the rate of about  $2\frac{1}{2}$  miles an hour the heat production is almost exactly the same whether the dog has had no food or whether 70 gm. of glucose has been administered. In the resting dog 70 gm. of glucose would have increased the heat production 6 calories. The experiment proves the economical use of carbohydrate during periods of work. On the contrary, when 700 gm. of meat were given and the dog was compelled to run, the heat production was increased by that quota which would have been added from the specific dynamic action of the protein metabolized."

# ANIMAL PRODUCTION.

Alfalfa silage, O. E. Reed and J. B. Fitch (Kansas Sta. Bul. 217 (1917), pp. 3-19, figs. 2).—Experiments conducted in 1914 and 1915 on the preservation of alfalfa in silos are reported. The silos were 7 ft. in diameter and 16 ft. in height and held about 10 tons of silage each. One of the silos was filled each year with alfalfa alone, another with rye alone, and the others with alfalfa in combination with corn chop, blackstrap molasses, straw, sweet sorghum stover, or green rye. A palatability test was made each year to see how cattle would relish the various combinations. Chemical analyses were made each year of the silages and of the mixtures from which they were made.

The silos were filled in May, 1914, the alfalfa used being the first cutting, cut when about one-tenth in bloom, and they were opened in January, 1915. The results were not entirely satisfactory, due in part to the fact that there was not sufficient weight in the silos to cause thorough filling and packing and also to the fact that the silos were not entirely air-tight. In the palatability test silage from each of the silos was placed in a separate feed bunk in a feed lot to which 40 beef cattle had access. The cattle showed their preference for the mixtures in the following order: Alfalfa and molasses (17:1), alfalfa and corn chop (13:1), alfalfa alone, alfalfa and rye (1.5:1), alfalfa and molasses feed (11:1), alfalfa and straw (4:1), and rye alone. Analyses of the silage used in this test showed that the moisture content of all the silages was low with the exception of alfalfa and rye.

Before filling the silos the second year they were painted on the outside and inside, thick asphalt paint being used on the inside. In order to pack the silage more firmly and prevent such a large amount of silage from being spoiled, additional weight was obtained by placing bags of sand on top of the silage after the silos were filled. They were filled in the spring of 1916 and opened in December, after standing 6.5 months. There was only about 8 in. of spoiled silage on the surface of each silo, and the silage was in much better

condition than in the previous test. In a palatability test conducted for 12 days on the plan of the previous year the silage mixtures were preferred by the animals in the following order: Alfalfa-molasses (20:1), alfalfa-molasses (10:1), alfalfa and corn chop (10:1), alalfa and rye (2:1), alfalfa and sweet-sorghum stover (6:1), and alfalfa alone. Very little difference was shown between the first five mixtures. In a few cases the alfalfa and sorghum stover seemed to be preferred to the alfalfa and corn chop and alfalfa and rye silage. The poor quality of the sorghum stover accounts for the fact that the alfalfa and sorghum stover silage was not relished at times. The cattle ate very little of the alfalfa silage alone.

No attempt was made either year to determine the feeding value of the different mixtures used. A study of the chemical composition of the silages shows that both years those containing the highest percentage of acid were most palatable to the cattle, with the exception of rye alone.

Sudan grass silage, C. K. Francis and W. G. Friedemann (Oklahoma Sta. Bul. 115 (1917), pp. 8, figs. 2).—This bulletin gives results of experiments on the preservation of Sudan grass silage in a steel silo. The Sudan grass was cut when about one-sixth of the plants had reached the milk stage. The composition is given of Sudan grass hay as compared with other hays and of Sudan grass silage and corn silage. It is noted that the composition of Sudan grass silage is very similar to that of corn silage, except that the former averages about 33 per cent in fiber and the latter about 23 per cent.

Temperature records taken at several depths in the silo show that the maximum temperature was reached in about 21 to 30 days and that no great increases occurred thereafter. It is stated that the Sudan grass silage was fed to the college sheep and, "while proving a good feed, it did not appear to be relished by the animals so well as the corn silage, but quite as well as that made from other grain sorghums, and was relished much more in this form than as cured hay."

A study of methods of estimation of metabolic nitrogen, E. B. Forbes, C. E. Mangels, and L. E. Morgan (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 12, pp. 405-411).—In the work reported, carried on at the Ohio Experiment Station, a basal ration of corn alone was fed to each of five pigs during the first period and nitrogenous supplements added to this corn ration in subsequent periods. In selecting the supplements an endeavor was made to choose foods the protein of which would probably be entirely digestible. Milk, blood albumin, and commercial dried egg albumin were used.

The analytical methods compared were the acid-pepsin method, the acid-pepsin and alkaline-pancreatin method, and the alcohol, ether, hot-water, and cold-lime water method suggested by Jordan. In the first two methods it is assumed that by the use of digestive enzyms the nitrogen which has been digested, absorbed, and returned to the feces may be separated from the indigestible nitrogen, and that there is no further digestion during the course of the estimation of that part of the protein which escaped digestion in the alimentary tract of the experimental animal. It is noted that there is no means of proving the truth of this assumption. The experimental methods are described.

The results show that the apparent digestibility of corn, based on the total nitrogen of the feces, is about 75 per cent. The results of the acid-pepsin method make it appear that the real digestibility is about 92 per cent, and the pepsin-pancreatin method, about 96 per cent. Jordan's method yielded appreciably lower figures, averaging 86 per cent. The results of the acid-pepsin

<sup>&</sup>lt;sup>2</sup> Maine Sta. Rpt. 1888, pp. 196, 197; abs. in U. S. Dept. Agr., Office Expt. Stas. Bul. 2 (1891), pt. 2, p. 60.

method indicate that 70 per cent of the nitrogen of the feces from corn is of metabolic origin, while those of the pepsin-pancreatin method and Jordan's method indicated 84 per cent and 46 per cent, respectively.

"All of the methods make the nitrogen of blood albumin appear more than completely digestible, even the apparent digestibility being over 100 per cent; thus, the feeding of blood albumin with corn seems to increase the digestibility of the corn protein to an extent more than sufficient to offset the incompleteness of digestibility of the protein of this supplement."

The apparent digestibility of skim milk varied from 95.97 to 104.44 per cent, the average being 99.15. The proteins of skim milk appear to be more nearly completely digestible by the acid-pepsin method than by the other methods.

It is indicated that "important inaccuracy seems to be inevitable in any determination of digestibility of supplementary foods in the usual way, by difference; and no other method seems more satisfactory. This applies equally to computations of real digestibility and of apparent digestibility (based on total nitrogen of the feces). The digestion coefficients for protein involved in the feeding standards of our reference works on animal production assume that the nitrogen of the feces is entirely an indigestible food residue. The rough measures afforded by the results of this study indicate that, as applying to the digestive capacities of swine, this assumption underestimates the digestibility of protein by about 20 per cent."

No significant differences were observed in the study of the effects on metabolic nitrogen of storage of the feces in a frozen condition for 20 days, with or without the addition of thymol, or air-drying the fresh material with or without thymol.

The acid-pepsin and the pepsin-pancreatin methods are considered to give results which are more nearly true than does Jordan's method. The latter does not digest the bacteria which may contain large proportions of the nitrogen of the feces and which presumably are more largely the product of digestible than of indigestible protein. The lack of an accurate scientific basis for the determination of the digestibility of protein is noted.

A study of the rate of passage of feed residues through the steer and its influence on digestion coefficients, P. V. Ewing and F. H. Smith (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 2, pp. 55-63).—In the investigations here reported, which were made at the Georgia Experiment Station, the attempt was made (1) to determine by means of digestion experiments the relationship between the moisture content of the feces and the digestion coefficients in order to see if there is a correlation between the time required for the passage of the food through the animal and the moisture content of the feces, (2) to follow more closely and directly by means of rubber markers the time required for passage of the feed residues through the steers, and (3) to determine the rate of passage by means of calculations based upon the intake of food and outgo of feces and the alimentary tract contents as ascertained on slaughtering.

In studying the problem by the first method essentially the digestion experiments already noted (E. S. R., 34, p. 169) were repeated. To avoid the complications in the calculations and results which would arise if comparisons were made of the data obtained while on different rations, studies were made on the correlations between the high and low moisture contents of the feces and the corresponding digestion coefficients where the same rations were employed. The correlations, as obtained from the results of the two series of digestion experiments each made in duplicate, indicate that with a higher moisture content of the feces there is a more complete digestion of all nutrients except nitrogen and fat. Commenting on the weakness of this method the authors state that "it

still remains to be proved definitely that the rate of passage of feed residue through the steer can be measured by the moisture content of the feces. Our work has shown that if a high moisture content of the feces is indicative of rapid passage then the apparent digestion is more complete probably for all the nutrients with the more rapid passage and less complete with the slower movement. Unfortunately, the method of study shows only the relationship and not the extent of the variation in digestion associated with a high moisture content."

In studying the problem by the second method soft rubber discs cut from heavy rubber tubing were fed at the beginning of a ten-day digestion trial and a count was made of them as they appeared in the feces. Some of the indicators appeared within 12 hours, while others were recovered as late as 60 days following, and still others never came out until the steers were slaughtered. While this method proved impractical, the slaughter tests showed that hard particles of feed and foreign substances were especially prone to become delayed in transit either in the reticulum, in the fourth, or true, stomach, or in the first few ventral folds of the duodenum. The coarse feeds and roughages retard the rate of passage of feed residues, a point proved conclusively by the slaughter tests. In connection with this method the use of 60 or 120 gm. per steer daily of calcium carbonate or magnesium sulphate exerted no appreciable effect upon the rate of passage of feed residue or upon the digestion coefficients.

Studying the problem by the third method, an accurate measure of the time required for the passage of the residue of feed was obtained by use of a formula. The inaccuracies of the method arising from certain metabolic processes are recognized, but it is stated that their influence would be no greater on these results than on the digestion coefficients, if as much.

The data obtained by this method indicate that with the rations used and the quantities fed the time required for the passage of the feed residues through the animals varied from 2.9 to 5.2 days. "The two most important factors determining the rate of passage are the nature of the ration and the amount fed. Coarse roughages seem to require a considerably greater time than the more finely ground concentrated feeds. . . . As to the influence of quantity, it appears that, when the coarse feeds were fed, a smaller quantity required a greater time for passage of the residues, but when the feed was a concentrate in pulverized form the variation was not so pronounced. . . . In dealing with the influence which the rate of passage of the feed residue may have had on the digestion coefficients we are unable definitely to attribute changes to the rate of passage, and at best it can only be said that associated with the more rapid passage there occurred an apparent gain in the digestibility of the ash, negligible results in the case of nitrogen, a decided loss in the digestibility of the crude fiber, a gain in the case of the nitrogen-free extract, and negligible results in the case of fat."

[Feeding experiments with beef cattle], D. T. GRAY (North Carolina Sta. Rpt. 1916, pp. 31-34).—To ascertain the best feed for wintering stock cattle, 67 grade steers were fed varying amounts of cottonseed meal and corn silage for 148 days at the station farm during the winter of 1915-16. The steers in lot 1 were fed an average daily ration of 20 lbs. of corn silage and 1 lb. of cottonseed meal, those in lot 2 an average ration of 23 lbs. of corn silage, those in lot 3 an average ration of 20 lbs. of corn silage, and those in lot 4 an average ration of 20 lbs. of corn silage and 0.5 lb. of cottonseed meal. During the last 44 days of the experiment all the lots also received 5 lbs. of corn stover per head daily. The steers in the first lot lost 16.2 lbs. during the entire

period, those in the second lot 52.9 lbs., those in the third lot 72.2 lbs., and those in the fourth lot 69.4 lbs.

In a similar experiment at the Iredell substation one lot of steers wintered on a daily ration of 20 lbs. of corn silage and 1 lb. of cottonseed meal gained 24 lbs. per head in 160 days. Another lot on a daily ration of 20 lbs. of corn silage alone lost 55 lbs. per head during the same period.

Work was carried on at the Edgecombe substation during the past winter to determine the best feeds for wintering beef calves, especially to see if cottonseed meal could be fed profitably. One lot of calves averaging 340 lbs. each in weight gained 19 lbs. per head in 98 days on an average daily ration of 15 lbs. of corn silage and 1 lb. of cottonseed meal. Another lot averaging 321 lbs. each in weight lost 16 lbs. per head during the same period on an average daily ration of 15 lbs. of corn silage alone. With silage at \$4 and cottonseed meal at \$40 per ton, the respective feed costs per calf were \$4.90 and \$2.94. The cottonseed meal did not injure the calves in any way.

At the station farm the attempt is being made to determine the amounts of cottonseed meal that can be safely fed to growing calves, with special reference to the kinds of roughage and antidotes. During the past winter 20 grade Jersey calves weighing from 150 to 450 lbs, each were divided into four lots and fed the following daily rations: Lot 1, cottonseed hulls and 1 lb. of cottonseed meal per 100 lbs. live weight; lot 2, cottonseed hulls and 1 lb. per 100 lbs. live weight of a mixture of cracked corn and cottonseed meal (1:1); lot 3, a mixture of beet pulp and cottonseed hulls and 1 lb. of cottonseed meal per 100 lbs. live weight; and lot 4, the same as lot 1 plus 1 qt. of iron sulphate solution per pound of cottonseed meal. This experiment was closed May 1, as one of the calves in the third lot died on April 12 as a result of cottonseed-meal poisoning and several of the other calves were losing their sight. The calves in lots 2, 3, and 4 were then turned on pasture and weighed again on October 31. All of them showed subsequent gains for the summer, and their eyes had apparently entirely recovered from the trouble. A repetition of the above experiment ended with practically the same results.

In a cooperative experiment in Haywood County the attempt is being made to solve the problem of maintaining beef cattle through the winter with a view to finishing on pasture the subsequent summer. During the past winter 114 stockers were divided into five lots and wintered for 119 days as follows: Lot 1 was fed a daily ration of 3.15 lbs. of ear corn and 11.4 lbs. of a mixture of corn stover, hay, and straw; lots 2 and 3, a daily ration of 18 lbs. of corn silage and 6 lbs. of the hay mixture; lot 4, pasture alone; and lot 5, which consisted of calves averaging 270 lbs. each in weight, a ration of 0.5 lb. of shelled corn and 0.5 lb. of cottonseed cake. The stockers in lots 1, 2, 3, and 4 averaged from 762 to 813 lbs. each in weight. During the winter the cattle in the first three lots lost in weight 34, 41, and 40 lbs., respectively, per head, while those on pasture alone gained 26 lbs. each. The calves gained 9 lbs. each. Counting pasture at \$1 a month per animal and the other feeds at local prices, it cost \$12.14 to winter each steer in the first lot, \$7 in lots 2 and 3, \$5.30 in the winter pasture lot, and \$4.18 to feed each one of the calves.

The cattle were placed on summer pasture from April 13 until August 31, lot 1 also receiving 4 lbs. of cottonseed cake per head daily. All the steers made good gains, but those fed cottonseed cake did not make much more rapid gains than those on pasture alone and it did not pay to feed it. The steers in lots 2, 3, and 4 yielded a net profit of \$21.63, \$20.94, and \$24.02 per head, respectively, while the steers in lot 1 yielded a net profit of only \$13.01 each.

Sheep, D. T. GRAY (North Carolina Sta. Rpt. 1916, pp. 34, 35, 36).—Two years' work on the effect of cottonseed meal upon the health and reproductive organs of breeding ewes showed no detrimental results from a ration of cottonseed meal and cracked corn (2:1). In the work of crossing Barbado sheep with those of the Shropshire and Merino blood, wool from the cross-bred animals was sold the past season for the same price as the wool from the Shropshire and Merino ewes. The Barbado sheep have not proved immune to the ravages of the stomach worm.

At the Iredell substation a lot of breeding ewes kept in shed or corral during the winter of 1915-16 and fed corn silage and a mixture of cracked corn, cotton-seed meal, and wheat bran (2:1:1) gained about 5 lbs. per head. Another lot pastured during the winter on a meadow from which hay had been cut gained 20 lbs. each. The cost of wintering the barn-fed ewes was about twice that of the lot on pasture. In the spring the ewes were all sheared, the wool selling at 36 cts. per pound, or \$2.99 per ewe, which was about the cost of wintering ewes on good pasture.

The management of farm flocks in Idaho, E. J. Iddings (Idaho Bul. 96 (1917), pp. 20, figs. 9).—This bulletin gives general information and suggestions for the management of farm flocks of sheep under Idaho conditions.

Are sheep profitable in winter? C. D. Woods (Maine Sta. Bul. 260 (1917), pp. 86-92).—A two years' progress report is given of the experiment with grade Hampshire sheep at Highmoor farm, already noted (E. S. R., 33, p. 73).

On the flock of 73 ewes, 3 rams, and 22 ewe lambs there was a loss of \$375.55 during the year ended October 31, 1915, the estimated value of manure being credited. During the year ended October 31, 1916, the flock was kept at a loss of \$207.56, no account being taken of manure, or allowing full value for manure and omitting overhead charges, a credit balance of about \$100 on the flock for 1915-16.

Family performance as a basis for selection in sheep, E. C. RITZMAN and C. B. DAVENPORT (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 2, pp. 98-97).—An outline is given of a system of selection on the basis of family performance being used in sheep-breeding work at the New Hampshire Experiment Station.

By "family" is meant the brothers and sisters and the two parents of the individual being studied. The aim of these breeding experiments being to produce a race of sheep that will combine good qualities of conformation, size, and wool, weights are assigned to various quantities which are thought to be correlated with the traits that are desired. The families from which individuals are to be selected are rated according to the average weights obtained in grading. In the selection of breeding rams, if the individual belonging to the "best" family is sickly or has any physiological quality that would interfere with its success as a breeder, the male from the next higher family may be preferred—that is, selection is made primarily on the basis of family performance, but the somatic insufficiency of the individual is permitted to veto the choice based on family alone. It has been found, however, that the best individuals usually come from the families that stand high in the scale.

The use of the method is illustrated in a particular case. The experiment has not yet proceeded far enough to show definite results, but the authors state that "the uniformity of the progeny and the high quality already shown by the earlier generations give us every reason for confidence that this method of selecting by family performance in place of individual traits is well worth the extra trouble it entails, if, indeed, it is not indispensable."

Digestion experiments with pigs, with special reference to the influence of one feed upon another, and to the individuality of pigs, H. S. Grindlet, W. J. Carmichael, and C. I. Newlin (Illinois Sta. Bul. 200 (1917), pp. 55-94, figs. 4).—The objects of the experiments reported in this bulletin were (1) to determine the influence of one feed upon the digestibility of the nutrients of another feed, (2) to study the individuality of pigs as to the thoroughness with which they digest their feed, and (3) to determine the coefficients of digestibility of the nutrients of the following rations: Wheat middlings, ground corn, ground barley, wheat middlings and ground corn (1:1), ground barley and ground corn (1:1), and tankage and ground corn (1:7.5). The feeding stalls used in these experiments were large enough to allow the pigs to turn around freely and were raised some 3 ft. from the floor to enable an easy collection of the urine. The feecs were collected in rubber-lined canvas bags held in place by specially constructed harness. Illustrations are given of the digestion harness and of the feeding stalls.

Each of the rations was fed for two 10-day periods. Each test period was preceded by a preliminary period of from 25 to 32 days during which the pigs were accustomed to the test rations and to the stalls and harness. Four 7-months-old pigs were used in each of the series, those in 1913-14 being cross-bred Berkshire-Chester Whites, all from the same litter, and those in 1914-15 cross-bred Duroc Jersey-Poland Chinas, all from the same litter. Analyses are given of the feeds and feces.

The following table gives the average coefficients of digestibility of the rations fed in these experiments:

Digestion	coefficients	of	rations	when	fed	to	swine.

Ration.	Number of experi- ments.		Protein.	Ether extract.	Nitrogen- free extract.	Crude fiber.
Wheat middlings. Ground corn. Ground barley. Wheat middlings and ground corn (1:1). Ground barley and ground corn (1:1). Tankage and ground corn (1:7.5).	8	Per cent. 74.4 87.1 70.8 79.1 80.9 86.0	Per cent. 80.0 74.5 54.0 77.3 66.5 74.8	Per cent. 85.4 68.3 33.0 83.4 67.8 80.8	Per cent. 81. 2 92. 1 81. 2 85. 9 88. 9 92. 2	Per cent. 21.0 34.8 14.1 12.1 15.0 51.2

Discussing the influence of one feed upon the digestibility of another feed as indicated by results obtained in these experiments, the authors conclude, "first, that the coefficients of digestibility of feeds calculated indirectly by subtracting the weights of the digestible nutrients of one feed as directly determined in other periods from the corresponding values for two feeds combined may be, and probably often are, decidedly inaccurate, and, second, that the weights of the digestible nutrients of a mixed ration calculated by the use of the coefficients of digestibility of the nutrients obtained directly for the individual feeds when fed alone may be decidedly inaccurate. It, therefore, seems evident from these considerations that, in order to obtain accurate results for the cofficients of digestibility of mixed rations, digestion experiments should be made directly upon the mixed rations as fed. In other words, in the future, coefficients of digestibility of the nutrients for mixed rations should be obtained and reported, rather than merely those for the individual feeds composing the rations."

The following table is a summary of the average results, which show the influence of one feed upon the digestibility of another feed:

Coefficients of digestibility of feeds, directly and indirectly determined.

Ration.	Number of experi- ments.	Dry sub- stance.	Protein.	Ether extract.	Nitrogen- free extract.	Crude fiber.

Calculated from direct determinations of coefficients of individual feeds.

Data are also tabulated showing the thoroughness with which each pig digested its feeds, from which it is concluded that "under conditions that are practically identical throughout the same experiment, the coefficients of digestibility of the nutrients of a number of different rations show significantly higher values for some pigs than for others. However, the differences in the coefficients of digestibility of the nutrients of the same feeds by the different pigs are probably too small to be considered of much, if any, practical or economic importance."

The digestibility of some Arkansas feeds for hogs, J. B. RATHER (Arkansas Sta. Bul. 133 (1917), pp. 16, fig. 1).—The results of digestion experiments on hogs are reported, including analyses of the feeds and a description of the digestion crate used in the experiments. The following table gives the coefficients of digestibility as determined:

Coefficients of digestibility of various feeding stuffs.

Number of trials.	Kind of feed.		Ether extract.	Crude fiber.	Nitrogen- free extract.

Pork production on irrigated lands in western Nebraska, J. A. HOLDEN (Nebraska Sta. Bul. 159 (1917), pp. 4-31, figs. 3).—Results of grazing experiments with hogs at the Scottsbluff experiment farm from 1912 to 1916, inclusive, are reported. Results secured from 1912 to 1915, inclusive, have been noted from another source (E. S. R., 36, p. 767).

<sup>&</sup>lt;sup>2</sup> Calculated from indirect determinations of coefficients of individual feeds.

In 1916 corn and ground barley were compared as supplements for alfalfa pasture. Although the one acre of pasture on which these tests were made was severely damaged by wind and hail storms, the results were fairly satisfactory and added strength to the previous years' data which showed that ground barley is equal to shelled corn as a hog feed. For the entire season the gain from the corn lot was 3,142 lbs., and from the barley lot 2,701 lbs. The corn lot consumed 2.74 lbs. of corn and the barley lot 2.92 lbs. of ground barley for each pound of gain made. When the gains made are figured at 7 cts. per pound and the lots charged \$1.07 per hundredweight for corn and \$1 for ground barley, the net returns for the one-acre alfalfa pastures were \$127.84 where corn was ted and \$110.11 where barley was fed. The pasture of the barley lot, however, was more severely damaged by the windstorms and one of the shoats in this lot became sick 28 days after the experiment began and was removed.

Sows and their litters grazed on alfalfa pasture with 2 lbs. of corn per 100 lbs. of live weight made a gain of 1,285 lbs. and a net return of \$57.20 per acre in 1916. The average for the five years in these tests, in one of which barley was used instead of corn, was 1,516 lbs. of gain and a net profit of \$63.11 per acre.

In an experiment which lasted two months in 1916 where corn and alfalfa pasture were compared with corn alone in a dry lot for finishing shoats for market, 13 acres of pasture supplemented with 9,677 lbs. of corn produced 2,497 lbs. of pork, and 11,300 lbs. of corn on dry lot produced 2,202 lbs. of pork, or a gain of 25.8 lbs. on pasture and 19.5 lbs. on dry lot per 100 lbs. of corn.

Results in 1916 in hogging corn without supplementary feed showed a gain of 840 lbs. of pork worth \$58.80 per acre, or \$1.56 per hundredweight for the estimated yield of corn. The average gain per acre in four years of these tests was 882 lbs. of pork worth \$61.74 per acre, or \$1.52 per hundredweight of the estimated yield of corn.

[Feeding experiments with pigs], D. T. GRAY (North Carolina Sta. Rpt. 1916, pp. 23-31).—At the Edgecombe substation 18 pigs weighing 87 lbs. each were pastured on 5 acres of soy beans for 60 days. In addition to the pasture they received a small amount of corn and tankage (9:1). As a check 3 pigs were fed a full ration of corn and tankage (9:1) on dry lot. The pigs on soybean pasture gained 1.38 lbs. per head daily at a cost of 4.96 cts. per pound of gain and returned a value of \$19.25 per acre for the soy beans, the yield of which was below normal. The pigs on dry lot gained 1.28 lbs. each daily at a cost of 5.6 cts. per pound of gain.

To determine the relative value of peanuts and soy beans as grazing crops for pigs, 1.65 acres of soy beans and 1.72 acres of peanuts were planted in the spring of 1915 at the Pender substation. Nine pigs averaging 112 lbs. each were turned into each field September 16 and given a half ration of corn. The soy beans afforded feed for the 9 pigs for 61 days, but an equivalent area of peanuts afforded grazing only 36 days. The soy bean-fed pigs gained an average of 0.98 lb. per head daily at a cost of 5.2 cts. per pound of gain. The peanut-fed pigs gained 1.36 lbs. per head daily at a cost of 5.41 cts. per pound of gain. Deducting the cost of grain the soy beans produced \$18.80 and the peanuts \$16.61 worth of pork per acre.

In an experiment to test the relative value of peanuts damaged in the shock and peanut meal for pigs at Edgecombe, 30 pigs averaging 98 lbs. each were divided into three lots and fed for 149 days, beginning January 25, 1916. The pigs in the first lot were fed a ration of corn and shorts (2:1), those in the second lot corn and damaged peanuts (2:1), and those in the third lot a ration of corn and peanut meal (2:1). Those in the first lot gained 0.69 lb. per head daily at a cost of 10.35 cts. per pound of gain, those in the second lot 0.71 lb. at a cost of 9.83 cts., and those in the third lot 0.81 lb. at a cost of 8.81 cts.

The waste peanuts were marketed by means of these hogs at more than 75 cts. per bushel.

In a preliminary experiment at the main station as to the relative value of wheat shorts, soy-bean meal, and peanut meal as supplements for corn, pigs averaging about 43 lbs. each were fed for 140 days in very small cement-floored lots. The pigs fed corn and shorts (2:1) gained an average of 0.29 lb. per head per day at a cost of 19.8 cts. per pound of gain, those fed corn and soy-bean meal (2:1) gained 0.44 lb. at a cost of 11.79 cts., and those fed corn and peanut meal (2:1) gained 0.37 lb. at a cost of 14.56 cts. In this test corn was valued at \$1 a bushel, soy-bean meal at \$40 a ton, and peanut meal at \$30 a ton.

Continuing the work on the use of iron sulphate and citrate of iron and ammonia to neutralize the effects of cottonseed meal upon hogs (E. S. R., 34, p. 79), it was found that while these chemicals did not completely overcome the toxic effects of cottonseed meal, gains were more satisfactory where they were used.

Tests were made on the feed and labor cost of raising pigs to weaning time at eight weeks of age. At Edgecombe with sows that raised an average of 5 ½ pigs the cost was \$1.94 per pig and the weight at weaning time averaged 24.3 lbs. At Pender the sows raised an average of 6½ pigs each, averaging 28.8 lbs. each in weight and \$3.34 in cost at weaning time. At the Iredell substation the sows raised an average of 6½ pigs each, averaging 31.8 lbs. in weight and cost \$2.24 each.

Extensive experiments are being made by the station on the softening effects of peanuts, soy beans, and mast upon the fat of hogs. In this work corn-fed hogs are used as a standard, it having been found that the melting point of the lard from the kidney fat of hogs fattened on corn alone is approximately 43° C. In a cooperative experiment hogs were grazed on waste peanuts for 82 days, at the end of which time their bodies were very soft. During the finishing or hardening period of 26 days the hogs were fed on corn alone and corn in combination with various amounts of cottonseed meal, but in none of the lots was the average melting point of the leaf lard of these hogs as high as 40° after the hardening period. At Pender a lot of pigs was grazed on soy-bean pasture supplemented with a partial ration of corn for 61 days, when the melting point of the leaf lard of two of the pigs averaged 37°. The remaining pigs were finished for 41 days on corn alone, and the average melting point of the leaf lard of these pigs was 39.8°. With another lot pastured on peanuts and fed some corn in addition for 36 days the average melting point was 33.4°, while the remaining pigs of this lot, after being finished for 66 days on corn alone, showed a melting point of 37.2°. At Edgecombe the leaf fat of pigs fed in dry lot on corn and tankage (9:1) for 60 days had a melting point of 43.3°, while in other pigs fed this ration supplemented with soy-bean pasture for 60 days it was 33.3°. The remaining pigs in the soy-bean lot were finished in dry lots for 21 days, when the lards taken from those finished on corn and tankage had a melting point of 35.6°, and from those finished on corn and cottonseed meal 38.5°. The results of more recent work indicate that soft-bodied hogs can be brought back to normal in from 32 to 49 days when corn is fed in conjunction with cottonseed meal,

Are swine profitable in winter? C. D. Woods (Maine Sta. Bul. 260 (1917), pp. 92-94).—In an experiment on the care of manure noted on page 628, it was necessary to keep the manure well worked over and compacted to prevent losses from heating. The experiment here reported was undertaken to determine whether swine would perform this work.

A brood sow and 14 2-months-old pigs were placed on the manure December 1, 1915, and were kept there until June 7, 1916. They were fed cooked turnips and ground feed, and some whole corn was scattered over the manure at times

to keep the swine at work stirring the manure. Reckoning the turnips at 15 cts. per bushel, corn at \$30 per ton, corn meal at \$31 per ton, middlings at \$27 per ton, and labor at 15 cts. per hour, and crediting the sow and shoats at the end of the experiment at 8 cts. per pound, live weight, increased by a litter of 8 pigs at \$2 each, and \$27 for manure, there was a profit of \$23.68, or a return of 15 per cent on the whole investment. Moreover, the manure in the pit was thoroughly worked and in excellent shape for application to the land.

Orokinase and salivary digestion studies in the horse, C. C. Palmer, A. L. Anderson, W. E. Peterson, and A. W. Malcomson (Amer. Jour. Physiol., 43 (1917), No. 3, pp. 457-474).—The name orokinase is proposed by the senior author, at the Minnesota Experiment Station, for the enzym produced in the mouth and found in the saliva which activates the saliva of the horse. Saliva obtained from the parotid ducts or extracts of the salivary gland was found not to digest starch, while mixed mouth secretions obtained from an esophageal fistula were found to have a very powerful amylolytic action. The amylolytic action of mixed horse saliva was equal to that of human saliva on cooked starches and greater on raw starches. The saliva collected from the mouth was hardly ever as powerful as that obtained from an esophageal fistula.

Attempts were made to activate artificially fistula saliva or gland extracts, but these were unsuccessful. The gland extracts, however, became self-active with age. Considerable reducing sugar in food caught from an esophageal fistula a few minutes after feeding a diet of raw corn and oats was demonstrated. It is noted that "salivary digestion started in the mouth is very likely continued in the stomach, and this digestion is more important in the horse than most investigators have been lead to believe."

The amylolytic action of parotid fistula saliva was studied by methods previously noted by Palmer (E. S. R., 36, p. 82).

[Cottonseed meal for work horses and mules], D. T. Gray (North Carolina Sta. Rpt. 1916, pp. 46, 47).—At the Iredell, Pender, and Edgecombe substations the work horses and mules have been divided into two lots, one lot receiving no cottonseed meal and the other lot the same kind of ration, except that cotton-seed meal makes up a part.

It has been found that "while cottonseed meal can be used in very limited amounts, we can not, as a rule, induce a horse or mule to use more than 1 lb. a day for any length of time. This 1 lb., however, has proved to be an economical addition to the ration, and has also had much to do with maintaining the horses and mules in better condition. The saving in money, however, is not the chief advantage in using cottonseed meal, or at least it does not appear so at the present time. It seems that the chief advantage will be that the horses which eat cottonseed meal stay in better condition. This is indicated plainly during the spring months, as the animals which eat cottonseed meal shed off earlier and smoother than those which do not eat it."

Licensed stallions in Utah during the season of 1916, W. E. CARROLL (Utah Sta. Circ. 24 (1917), pp. 3-25, fig. 1).—Tables are given showing the distribution of licensed stallions and jacks in the State, the number of licensed animals in each county and the percentage which are pure bred, and the distribution among the various breeds.

[Poultry investigations], D. T. Gray (North Carolina Sta. Rpt. 1916, pp. 43-45).—In tests on the cost of raising chicks to eight weeks of age it was found that to produce 1 lb. of gain with the Mediterranean and Continental breeds it required 2 lbs. of feed, and with the English and American breeds 2.1 lbs. of feed. At the end of eight weeks chicks of the former classes averaged 1.2 lbs. in weight, while those from the latter classes averaged 1.6 lbs. It cost slightly over 8 cts. per pound to produce gains in all the breeds.

In fertility experiments it was found that ordinarily from 80 to 90 per cent of the eggs are fertile when cocks are continually with the hens, and from 80 to 90 per cent of these eggs hatch. When cocks were removed from the hens the fertility of the eggs declined rapidly, no fertile eggs being found after from 15 to 18 days. When cocks were placed with laying hens fertile eggs began to appear after the fifth or sixth day.

An experiment was begun November 1, 1915, with three lots of hens to determine the effects of continued feeding of cottonseed meal upon the health, vigor, and egg production. Rations were fed made up of 30 per cent, 5 per cent, and no cottonseed meal, respectively. During the first year 26, 12, and 10 per cent of the respective flocks died. There has not been so far a marked difference in the amount of eggs produced.

Eight different breeds and some mixed lots were compared as to the amount of feeds eaten, the cost of feeds, and the amount of manure produced. Of the breeds tested, the Silver Campines consumed the least amount of feeds. In cost of eggs produced, the Buff Plymouth Rock was the most expensive breed. In this test the hens produced an average of 22 lbs, of manure per head per year.

In experiments in marketing eggs by parcel post and express it was found that such materials as sawdust, bran, and cottonseed hulls pack so closely that there is not sufficient spring to the material about the eggs, and about 10 per cent of the eggs are broken in transit. These materials were particularly unsatisfactory when breeding eggs were shipped. When the eggs were wrapped in soft paper, felt, moss, or prairie hay very few were broken.

At the Pender substation soy-bean meal practically took the place of rolled oats for chicks and was much cheaper. At the Edgecombe substation peanut meal proved a valuable feed for young chicks up to eight weeks of age. Chicks fed a ration of peanut meal, corn meal, and ground oats (1:1:1) and buttermilk weighed an average of a little over 1 lb. each at eight weeks of age, while those fed a similar ration with peanut meal omitted weighed only 0.7 lb. each.

Preparing poultry produce for market, F. G. ELFORD (Canada Expt. Farms Bul. 88 (1916), pp. 31, pl. 1, figs. 19).—In addition to notes on the need and value of preparing poultry for market and systems of marketing, this bulletin contains general directions for packing and shipping market eggs, for crate feeding, killing, plucking, packing, and marketing poultry, and for crating and shipping breeding stock and eggs for hatching.

Preserving eggs for home use, G. S. TEMPLETON (Alabama Sta. Circ. 36 (1917), pp. 39-42, fig. 1).—Brief directions are given for preserving eggs in water glass or sodium silicate.

#### DAIRY FARMING-DAIRYING.

Dairy investigational work, D. T. GRAY (North Carolina Sta. Rpt. 1916, pp. \$6-40).—Work has been carried on at the Pender substation for three years to determine the value of corn silage for milch cows. During the three winters the cows fed silage have produced 3.878 lbs. of milk more than those fed cottonseed hulls and corn stover. This was produced at a saving of \$11.42 in cost of feed.

A progress report is made of four years' work at Pender substation and near Greensboro in cooperation with farmers to test the value of a limited ration of cottonseed meal for wintering growing dairy calves. Each year one lot of calves was fed a grain ration of cottonseed meal alone and another lot a grain ration of cottonseed meal and bran (1:1). The roughage was the same for both lots. Summarizing the four years' work, during which the calves were upon experimental feeds for 553 days, it was found that the respective feed

costs were \$99.33 and \$98.88, while the calves fed no bran gained an average of 54.8 lbs. more per head. At Pender the same feeds were also compared as supplements for scant pasture for dairy heifers during the spring and summer. During the three summers this experiment has been running the calves fed cottonseed meal have made the better gains, but this ration was somewhat the more expensive.

Data on the cost of raising 22 calves at Pender show that when these calves were 6, 12, and 18 months old they averaged per head 264, 373, and 478 lbs. in weight, respectively, at total costs of \$13.57, \$26.12, and \$34.30. Four of the calves which attained the age of 30 months averaged 646 lbs. in weight at a total cost of \$52.06. These figures include market prices for feeds and \$1 per month each for pasture, no credit being made for manure. Cooperative experiments with farmers in Guilford and Forsyth Counties show a cost of \$31.58 to raise a dairy calf to the age of 12 months.

A study is being made at Pender relative to the feasibility of overcoming onion flavors in milk. In one case a strong onion flavor was found in the milk of a cow milked 19 hours after the onions had been eaten. It has been found that molasses fed in conjunction with other feeds materially weakens the onion flavor, but does not remove it completely. Other remedies being tried are charcoal, soda, mixtures of charcoal, soda and molasses, and patent preparations. These have been without effect, except that one of the patent preparations has caused some weakening of the onion flavor.

[Feeding experiments with dairy cattle], J. M. Scort (Florida Sta. Rpt. 1916, pp. 18-23).—In a comparison of sorghum silage and Japanese cane silage as supplements for wheat bran and cottonseed meal for dairy cows, ten cows were fed during four periods of 16 days each with four days between experimental periods for changing feeds. The cows were fed in lots of five by the reversal system. Those on sorghum silage produced 539.72 gal. of milk at a feed cost of 12.1 cts. per gallon and those on Japanese cane silage 509.74 gal. of milk at a feed cost of 12.8 cts. per gallon. In this experiment the silage was valued at \$4 per ton. All the cows gained slightly in weight during the test, there being no difference between the two rations in maintaining the animal's initial weight.

A comparison was also made of sorghum silage and sweet-potato silage as supplements for wheat bran and cottonseed meal. In this test ten cows were fed by the reversal system during two periods of 20 days each with three days for change of feeds. The five cows on sorghum silage produced 280.9 gal, of milk at a feed cost of 14.8 cts. per gallon. The five cows fed sweet potato silage produced 307.1 gal, of milk at a feed cost of 15.4 cts. per gallon. In this experiment sorghum silage was valued at \$4 and sweet-potato silage at \$13 per ton. Each of the cows gained in weight during the test. This work has shown that it is practicable to preserve sweet potatoes in the silo for cattle feeding and hog feeding purposes.

During the winter of 1915-16 sorghum silage and Japanese cane silage were compared for feeding young cattle. Grade Jersey heifers from 15 to 20 months old were fed for 60 days all the silage they would eat and 1 lb. of cottonseed meal each daily. The animals fed sorghum silage gained an average of 8.25 lbs. each during the 60 days, and those fed Japanese cane silage barely maintained their weights.

Feed and care of the dairy calf, R. S. Hulce and W. B. Nevens (Illinois Sta. Circ. 202 (1917), pp. 13, figs. 6).—Methods of feeding and care are given which have been found by experience to give good results in the rearing of calves.

The average weights at one day of age of calves born in the university herd are classified according to breed and sex as follows, the first figure under each breed being for females and the second for males: Jersey 59.7 and 62.4, Guernsey 68.8 and 70, Ayrshire 71.4 and 77.7, and Holstein 88 and 90 lbs. At the station a group of 20 Holstein heifers from birth to one year of age consumed 244 lbs. of whole milk, 860 lbs. of skim milk, 1,107 lbs. of grain, 1,067 lbs. of hay, and 1,669 lbs. of silage per head. These heifers averaged 92 lbs. at birth and 532 lbs. at one year and made an average daily gain of 1.2 lbs.

Selecting rations for dairy cows, G. C. White and K. B. Musser (Connecticut Storts Sta. Bul. 90 (1917), pp. 3-38).—The requirements to be considered in formulating dairy rations are discussed and tables are given showing the characteristics of some common feeds; the nutrients required by dairy cows for maintenance and milk production; the digestible nutrients, fertilizing constituents, and value of feeding stuffs; the average wholesale prices for 13 years of feeding stuffs in carload lots at Boston points; high and low prices of some common feeds by months for five years; cost per hundredweight of digestible nutrients at different prices for feeds, etc. Full directions are given for selecting and compounding rations, and suggestions are offered for analyzing the feed market.

Dairy feeding and the calculation of rations, L. S. RIFORD (New Jersey Stas. Circ. 73 (1917), pp. 15).—This circular explains briefly some common feeding terms, gives directions for the use of the feeding standard, and offers suggestions for the purchase of concentrates and the use of home-grown feeds.

Dairy herd [record], J. M. Scott (Florida Sta. Rpt. 1916, pp. 14-17, figs. 3).—Tables show the calving record, age and breed of cows, time in milk, milk and fat production records, and cost data of the station dairy herd during the fiscal year. Of 19 pure-bred and grade Jerseys being milked during the year, the highest yield was 5,907.7 lbs. of milk and 360.75 lbs. of fat. The cost of feed for this cow was \$94.86. Valuing butter at 40 cts. per pound and milk at 32 cts. per gallon, she returned a profit of \$124.95 over cost of feed.

Germ content of milk.—I, As influenced by the factors at the barn, M. J. PRUCHA and H. M. WEETER (Illinois Sta. Bul. 199 (1917), pp. 25-51, figs. 3).— The investigation here reported is a part of that begun by Harding et al. (E. S. R., 29, p. 878). Its purpose was to measure the collective influence of all the barn conditions and operations upon the germ content of the milk produced therein. The data were obtained in three dairy barns during the years 1914 and 1915. A description is given together with an illustration of the interior of each of the barns. The three barns "in a general way represent three classes of dairy barns, barn 1 being in excellent condition, barn 2 being good, and barn 3 poor. The difference between barns 1 and 2 as to cleanliness, however, was not very great. On the other hand, barn 3 would be classed as a dirty barn."

The utensils used were thoroughly steamed before each milking. In 1914 the udders of all the cows were wiped with a damp cloth previous to each milking, but in 1915 this practice was discontinued. All samples were taken from the milk of the individual cows when the milker brought it in pails from the barn into the adjacent milk room. The bacteriological examination of the milk was made by the plate method. In order to ascertain the extent of variation in bacterial count due to the laboratory methods employed, ten experiments were undertaken in each of which 100 plates were seeded with the same milk. None of the individual counts varied much more than 25 per cent from the average.

A total of 1,665 samples were taken from 138 cows. Data from the analyses of these samples are tabulated. Among the samples from barn 1 the lowest

germ content was 17 and the highest was 218,250 bacteria per cubic centimeter of milk; in barn 2 the lowest was 3 and the highest was 33,000; and in barn 3 the lowest was 307 and the highest was 63,835. "These are wide limits of variation in the germ content of milk produced under uniform barn conditions."

The following table shows the grouping of all milk samples according to germ content and the average germ content of the milk from the three barns:

Arrangement of milk samples according to germ content and average number of bacteria per cubic centimeter.

Barn.	Below 1,000 per cubic centi-	Between 1,000 and 5,000 per cubic cen- timeter.	Between 5,000 and 10,000 per cubic cen- timeter.	Between 10,000 and 50,000 per cubic cen-	Over 50,000 per cubic centi-	Average germ content per cubic centimeter of milk.	
	meter.			timeter.	meter.	1914.	1915.
I	472 405 19	297 153 127	56 4 57	29 5 34	6 0 1	2,140 973 6,189	3, 260 830 5, 050
Total	896	577	117	68	7	2,188 (Av.)	2,552 (Av.)

Most of the samples of high germ content in barn 1 came from a few animals. One of these animals persistently gave milk with high germ content and subsequent studies showed that her udder was the source of these large numbers of bacteria in her milk. Data are tabulated showing the average content of the milk of each animal for each of the two years. Of the 72 averages in barn 1, 30 were below 1,000 bacteria per cubic centimeter of milk, 35 were between 1,000 and 5,000, only 7 were over 5,000, and of these 7 only 2 were over 10,000. In barn 2, 30 of the 47 averages were below 1,000, and the highest average was only 3,599. In barn 3 all the averages were above 1,000 bacteria per cubic centimeter of milk, 11 were below 5,000, 6 were between 5,000 and 10,000 and 2 were over 10,000.

It is thus seen that in the production of milk of low germ content the udder of some cows may become the principal source of contamination. It is stated that "no conclusion can be drawn from the data concerning the relative importance of the practice of wiping the udders, as compared with the other sources of contamination in these barns. The data, however, do point to the conclusion that the wiping of the udders under the conditions obtaining in these barns did not affect the germ content of the milk to any appreciable extent."

Commenting on the results of this investigation, the authors state that it might be argued from the results obtained in barns 1 and 2 "that a dirty barn does not contribute more bacteria to the milk than a clean barn. Such conclusion, however, would be against a well-established fact. This apparent discrepancy is only a side issue to the general problem, and it would be a mere conjecture to attempt to explain it. The real significance of the results from these two barns lies in the fact that the number of bacteria in the milk from both barns was remarkably small, and that the difference in the conditions and the operations in the two barns exerted practically negligible influence upon the germ content of the milk.

"Even more significant are the results from barn 3. The average contamination here was 5,777 bacteria per cubic centimeter. This milk, so far as the germ content was concerned, would meet the requirements for certified milk, and yet the conditions of the barn as to cleanliness were such that it is doubtful whether the milk produced here would have been admitted to the milk supply of some cities. These results must not be construed as a defense of

dirty barns. They simply point to the fact that the large numbers of bacteria commonly found in milk do not have their origin in the barn."

Fishiness in evaporated milk, B. W. Hammer (lowa Sta. Research Bul. 38 (1917), pp. 235-246, fig. 1).—The author briefly reviews recent literature pertaining to fishy flavor in milk and butter and reports results of a study of the cause of the very fishy odor and flavor that had developed in one can of evaporated milk. From this can an organism was isolated that was capable of producing fishiness in milk, cream, or evaporated milk into which it was inoculated. In inoculated milk there was, in addition to the development of a fishy odor, a coagulation and a rapid digestion. The isolated organism when inoculated into butter, either directly or into sweet or sour cream either pasteurized or sterilized before churning, failed to produce fishiness. In some lots of butter, salt was used while other lots were unsalted. The counts made showed that the numbers of bacteria per gram deceased throughout the holding period with butter made from sour cream and with salted butter made from sweet cream, while with unsalted butter made from sweet cream there was an increase which was followed by a decrease.

A description is given of the organism under the name Bacillus ichthyosmius, apparently a new species closely related to the Proteus group. It is suggested that the organism, which fails to resist heat, may have gained entrance to this can after heating, probably through some hole in the metal which was sealed shortly after sterilization.

The manufacture of cottage cheese in creameries and milk plants (U. S. Dept. Agr., Bur. Anim. Indus. [Pub.], (1917), pp. 4).—This circular points out the advantages of pasteurizing skim milk for the purpose of controlling the flavor of cottage cheese, describes in brief the methods of manufacture, packing, and marketing, and gives an estimate of the yield of cottage cheese to be expected from skim milk.

Simple directions for making cottage cheese on the farm (U. S. Depi. Agr., Bur. Anim. Indus. [Pub.], (1917), pp. 3).—Brief directions are given for the utilization of skim milk for making cottage cheese on farms.

A substitute for litmus for use in milk cultures, W. M. CLABK and H. A. Lubs (U. S. Dept. Agr., Jour. Agr. Research. 10 (1917), No. 3, pp. 105-111).—
"The color changes which occur in litmus-milk cultures may be due to changes in the hydrogen-ion concentration of the medium, or to reduction, or even destruction of the dye. If it is the degree of acid or alkali fermentation which is sought, it is advisable to use an indicator which will not be affected except by a change in the hydrogen-ion concentration." Dibromoorthocresolsulfon-phthalein, for which the short name bromcresol purple is suggested, is said to fulfill this condition. The authors have described the preparation of this compound (E. S. R., 36, p. 111) and have suggested its use in the determination of hydrogen-ion concentration (E. S. R., 37, p. 506.) For ordinary indicator purposes a 0.04 per cent aqueous solution of the monosodium salt is recommended, but as a stock solution for the present purpose a solution of the salt containing 0.5 per cent of the acid is suggested. A method is given for the preparation of this solution.

In comparing litmus and bromeresol purple as indicators in milk cultures it is stated that "litmus undergoes a temporary reduction during sterilization in the presence of milk. Bromeresol purple does not. The coloring power of litmus is relatively weak; bromeresol purple in very high dilution is useful. Litmus and azolitmin are indicators of uncertain composition; bromeresol purple is a definite individual compound obtainable in crystalline form and therefore reproducible. Its cost is not excessive.

"The impurities of litmus preparations vary in their effect upon the  $P_{\rm H}$  of milk and often necessitate elaborate adjustment either of the litmus solution, of the milk, or of the mixture if reproducible color is to be obtained. Bromcresol purple, on the other hand, may be used with the assurance that, if other conditions are constant, it will always produce the same coloration. Some of the difficulty experienced in reproducing a particular initial color with either indicator is shown to be due to the changes in  $P_{\rm H}$  which occur when milk is sterilized by heat.

"The comparative value of litmus and bromcresol purple in milk cultures was tested with a variety of organisms. It was found that no change in reaction could be observed with litmus which could not be followed equally well with bromcresol purple. In many instances litmus was rendered useless by reduction or destruction while bromcresol purple continued to act as a true indicator of the hydrogen-ion concentration."

## VETERINARY MEDICINE.

Annual reports of the State veterinarian of Alabama, 1914 and 1915, C. A. CARY (Ann. Rpt. State Vet. Ala., 8 (1914), pp. 28; 9 (1915), pp. 48).—
These reports, dealing with the work of the years 1914 and 1915, respectively, include accounts of the occurrence of and control work with diseases of live stock, including tick eradication.

Report of the Montana Live Stock Sanitary Board and State veterinary surgeon for years 1915–16 ([Bien.] Rpt. Mont. Live Stock Sanit. Bd., 1915–16, pp. 50, pl. 1).—This report, dealing with the work of the year with infectious and other diseases of live stock, includes a discussion of tuberculosis free accredited herds, contagious abortion, etc., and gives a list of official dips and disinfectants, live stock sanitary board orders, regulations governing importation of live stock into Montana, etc. A short popular article on cattle lice in Montana, by R. A. Cooley and R. R. Parker, is included.

Diseases of domestic animals (*Rpt. Dept. Agr.* [N. H.], 34 (1915-16), pp. 85-99).—This reports upon the occurrence of and control work with infectious diseases of live stock in New Hampshire.

Annual reports of the chief veterinary officer for the years 1914 and 1915, S. STOCKMAN (Bd. Agr. and Fisheries [London], Ann. Rpt. Chief Vet. Off., 1914, pp. 62; 1915, pp. 12).—These report briefly upon the occurrence of and work with the more important diseases of animals during 1914 and 1915.

In the report for 1914 some cross-immunization tests with *Piroplasma bige-minum* and *P. divergens* are noted which indicate that animals immunized against *P. bigeminum* are not protected against infection by *P. divergens*, or vice versa.

For obtaining massive cultures of *Bacillus abortus* a medium prepared as follows was used: Five hundred gm. of raw potato in small pieces is macerated in 2,000 cc. of water, placed in an incubator for 12 hours at 60° C. and then strained through a flannel bag. To the filtrate, 10 gm. of meat extract, 10 gm. of salt, and 20 gm. of Witte's peptone are added. The mixture is steamed for 1 hour, strained through a flannel bag, rendered slightly alkaline, and again steamed for 1.5 hours. A slight precipitate results which is removed by filtration through paper. The filtrate is finally sterilized in the autoclave and kept as a stock solution. With the addition of 1 per cent of sugar and 1 per cent of glycerin the material constitutes an excellent liquid medium for cultivating the organism.

For making a solid medium, 60 gm. of agar is added to 2,000 cc. of the stock solution and melted in the usual way. After clarifying by the usual method,

the medium is again neutralized, if necessary, and grape sugar and glycerin added as for the liquid medium. The material is then sterilized in the autoclave, either in bulk or in culture flasks.

Immunity in its relation to the stock diseases of Southern Rhodesia, I. E. W. Bevan (Rhodesia Agr. Jour., 13 (1916), Nos. 5, pp. 640-651; 6, pp. 800-812, pls. 2; 14 (1917), No. 2, pp. 213-234, pls. 2).—This is a general review of the subject with special reference to the stock diseases of Southern Rhodesia.

Anaphylatoxin and anaphylaxis, F. G. Novy and P. H. DeKeuif (Jour. Amer. Med. Assoc., 68 (1917), No. 21, pp. 1524-1528).—This is a general summary of the studies previously noted (E. S. R., 37, p. 578).

The effect of temperature on the rate of complement fixation, J. Bronfenbernner and M. J. Schlesinger (*Proc. Soc. Expt. Biol. and Med.*, 14 (1917), No. 7, pp. 139, 140).—The authors have studied the relation between the temperature and the rate of fixation and have found that "if sufficient antibody is present in the serum (three to five units or more) fixation of two units of complement takes place within the first five minutes, provided the amount of antigen used contains several antigenic units. We find it possible to use this procedure for presumptive elimination of strongly positive sera from a large series of cases. One places in a tube 0.05 cc. of the patient's serum, adds the proper amount of antigen and salt solution and incubates at 37° C. in the water bath for five minutes, and then adds sensitized cells to test for free complement." Where a rapid fixation of complement is desired a temperature of 37° is indicated as being the best. One-half hour of incubation at this temperature is considered to be the most efficient for diagnosis.

Where the time element is of little importance, but complete fixation is desired, incubation in the ice box for from eight to ten hours is found to be the best. "These fixations on ice, however, may not be specific, for the reaction of fixation is so complete under these conditions that even traces of secondary circulating antigens and their corresponding antibodies may cause fixation of complement. The ice-box fixation can, therefore, be used only as a presumptive test to eliminate the negative cases."

For the fixation of complement at temperatures below the freezing point such a procedure was found to produce undesirable changes in the reagents, especially in the antigen, and was therefore unsuitable for the test.

The specific serum treatment of wounds, E. Leclainche and H. Vallée (Jour. Compar. Path. and Ther., 29 (1916), No. 4, pp. 283-290).—This is an English translation of the material previously noted (E. S. R., 35, p. 882).

Plants poisonous to live stock, H. C. Long (Cambridge: University Press, 1917, pp. VII+119, pl. 1).—A brief summary of the present knowledge of plants poisonous to live stock in Great Britain, with symptoms, toxic principles, and a list of the more important references to the bibliography in relation to each plant. The poisonous plants are dealt with under their respective orders, and accounts are given of plants suspected of being poisonous, the effects of plants on milk, plants which cause mechanical injury, and the classification of poisons. A bibliography of 267 titles is appended and a subject index included.

Potassium permanganate as an antidote for the effects of poisonous plants, C. D. Marsh (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 3, pp. 419, 420).— The author calls attention to the fact that for practical purposes the use of a drench of potassium permanganate in the case of ruminants poisoned by plants is without value, as previously shown (E. S. R., 35, p. 779). While potassium permanganate, tannic acid, or sodium bicarbonate would be logical antidotes for alkaloidal poisonings, they are effective only as they come into actual contact with the poisonous substances. It has been found experimentally that if the antidote is given repeatedly at intervals of 30 minutes or less

tt is effective, for it then attacks the poisonous substance as it passes through the abomasum.

Studies in forage poisoning, IV, R. GBAHAM and L. R. HIMMELBEEGER (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 2, pp. 164-187, figs. 6).—This report is based upon investigations conducted at the Kentucky Experiment Station and previously noted (E. S. R., 36, p. 581).

During the course of investigations in connection with a definite outbreak of forage poisoning various types of microorganisms that proved to be quite uniformly poisonous to horses and mules were isolated from oat hay. Among these was a spore-forming, Gram negative, aerobic bacillus which was pathogenic for horses and mules and less so for cattle, sheep, and goats, but to which guinea pigs, rabbits, and white mice were apparently immune. Sterile filtrates of this bacillus subsequent to daily intravenous injections in some experimental horses proved pathogenic and capable of exciting clinical manifestations somewhat analogous to affected animals in the original outbreak as the result of feeding on oat hay.

The bacillus previously noted (E. S. R., 36, p. 581) was isolated from silage in a remote outbreak of forage poisoning among cattle.

Cottonseed meal work, W. A. WITHERS (North Carolina Sta. Rpt. 1916, pp. 19, 20).—This is a brief review of investigations during the year of the toxicity of cottonseed meal which have confirmed the views previously presented (E. S. R., 34, p. 381) that gossypol is the toxic substance of cottonseed.

Blackleg filtrate, A. EICHHORN (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 3, pp. 406-413; Amer. Jour. Vet. Med., 12 (1917), No. 6, pp. 375-378).—The biological products proposed and used in blackleg are briefly reviewed. Preparation of a filtrate from media containing meat upon which the organism was grown until no more gas was produced, together with a procedure for its standardization, is noted.

The filtrate is considered to be an effective immunizing agent, conferring an active immunity which protects cattle against blackleg for as long a time as the germ-free extracts prepared from the juices of the tissues of affected animals. The losses incidental to vaccination with the powder or pellets are entirely avoided, since the preparation does not contain the blackleg germ.

The material in a concentrated form was found to retain its potency for almost an indefinite time. The necessity of the usual sterility tests of the filtrate, in order to guard against possible contamination, is indicated.

The virulence of the blood of animals affected with foot-and-mouth disease and immunity tests, G. Cosco and A. Aguzzi (Gior. Med. Vet., 66 (1917), No. 14, pp. 313-320).—This is a brief report of the investigation ordered by the Italian minister of the interior in 1916. The topics treated are incubation, fever, time of maximum virulence of blood, virulence of red blood corpuscles, minimum dose of blood, increase of virulence of red blood corpuscles, temporary infection through the mouth, intravenous injection, and immunity tests.

Allergic reaction of mallein for the diagnosis of glanders, E. Fava (Arch. Sci. Med. Vet. [Turin], 14 (1916), No. 1-12, pp. 1-131, figs. 27).—The author describes and submits experimental data obtained through the application of the subcutaneous, ophthalmic, and intrapalpebral mallein tests, and discusses the specificity of the intrapalpebral reaction and its advantages over the other methods of malleinization, the intrapalpebral test for the prophylaxis of glanders, and its application.

It is concluded in general that the intrapalpebral test posseses advantages over the other procedures for the diagnosis of glanders, the advantages being those essentially noted by other investigators.

Milk sickness, D. T. Grav (North Carolina Sta. Rpt. 1916, p. 36).—A brief statement of work by Curtis and Wolf (E. S. R., 37, p. 583).

Studies on the paratyphoid-enteritidis group.—III, Some cultural characteristics and their relation to host origin, C. Krumwiede, Jr., Josephine S. Pratt, and L. A. Kohn (Jour. Med. Research. 35 (1917), No. 3, pp. 357-366).—"The quantitative differences in the reduction of fuchsin, added to the fermentative results, especially of dulcit and arabinose, give fairly defined groups. This grouping is only suggestive in that it correlates to some extent with host origin, a correlation hitherto not observed. It also correlates with the primary or secondary invasive properties of the various types. As would be expected, the latter are much more heterogeneous.

"Some of the results do not correlate with agglutinative results and suggest the necessity of further study in relation to such correlation."

Studies on the paratyphoid-enteritidis group.—IV, The differentiation of the members of the paratyphoid-enteritidis group from B. typhosus with special reference to anaerogenic strains and observations on the fermentative characteristics of the avian types, C. Krumwiede, Je., and L. A. Kohn (Jour. Med. Research, 36 (1917), No. 3. pp. 509-518).—"The ability to produce acid from rhamnose is the essential characteristic of the paratyphoid-enteritidis group, differentiating both the aerogenic and anaerogenic members from B. typhosus. Additional cultural differences between B. typhosus, B. sanguinarium, and B. pullorum are presented. The agglutinative relationship of the strains studied is recorded. Observations are added on the low or latent avidity for carbohydrates in relation to variability and practical differentiation. Without due regard to these factors, erroneous differential significance reight easily be given to variation even among members of the fixed groups."

Effect of the injection of nonspecific foreign substances on the course of experimental rabies, W. H. Burmeister (Jour. Infect. Diseases, 21 (1917), No. 1, pp. 95-107).—"The injection of certain nonspecific substances (horse serum, serum globulin, egg white, egg yolk, broth, typhoid vaccine, or tuberculin) does not inhibit the course of experimental rabies in rabbits produced by nonattenuated virus. The seemingly beneficial effect of tuberculin in the early series of the experiments must be disregarded because of the survival of some control animals inoculated at a later date with the same virus. . . . Rabbits surviving an intracerebral inoculation of attenuated rabies virus (fixed or street virus) may become hypersensitive to a reinoculation of the same virus made in the same way."

Tuberculosis in camels, F. E. MASON (Jour. Compar. Path. and Ther., 30 (1917), No. 1, pp. 80-84).—The literature on the occurrence of tuberculosis in camels is briefly reviewed. Continuing the work previously noted (E. S. R., 29, p. 676), the author has examined and made bacteriological studies of a large number of camels slaughtered in the Cairo abattoir. The disease appears to occur chiefly in Egyptian camels and the causative organism to be of the bovine type.

The source, method of infection, course, distribution of lesions, and histology of lesions of tuberculosis in the camel are briefly discussed.

The subcutaneous tuberculin test with ordinary tuberculin was successfully employed on infected animals. Data relative to the variations in the normal temperature of camels are submitted.

Brisket disease, G. H. GLOVEB and I. E. NEWSOM (Colorado Sta. Bul. 229 (1917), pp. 3-8, figs. 3).—This is a revised and abbreviated edition of Bulletin 204, previously noted (E. S. R., 32, p. 781).

Report of the division of veterinary science, G. A. Roberts (North Carolina Sta. Rpt. 1916, pp. 55-57).—The principal work of the year was with conta-

gious abortion, some 2,500 cows and heifers in 70 herds at 35 different points in the State being examined. In agglutination and complement fixation tests of 203 samples of blood from cattle in various sections of the State 65 per cent gave positive reactions with one test or the other, 17 per cent negative reactions to both tests, and 18 per cent suspicious reactions.

Keratitis infectiosa in cattle (keratitis pyobacillosa), J. Poels, trans. by J. Kappeyney and A. R. Ward (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 4, pp. 526-531).—The author's investigations have led to the conclusion that Bacillus pyogenes is the specific cause of the infectious eye disease of cattle now existing in Holland, and that the two species of micrococci found present are secondary invaders. The author has used pyogenes serum as a prophylactic and as a curative agent with favorable results.

The life history of Hypoderma bovis and H. lineatum, S. Hadwen (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 4, pp. 541-544).—The observations here reported are based upon work at Agassiz, B. C. The principal differences between the two warble flies, both anatomically and biologically, are pointed out. It is thought that with H. lineatum several larvæ enter through the same opening in the skin.

Feeding lambs in the summer to prevent stomach worms, D. T. Grav (North Carolina Sta. Rpt. 1916, p. 35).—A first year's feeding experiment which was carried on to determine whether a heavy grain ration had any effect in overcoming the ravages of the stomach worm, in which 30 lambs were used, indicates "strongly that there is a very definite relationship between deaths by stomach worms and grain fed through the pasture season."

Hog cholera transmission through infected pork, R. R. BIRCH (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 3, pp. 303-330, figs. 3).—Detailed experimental data of a study on the effects of feeding susceptible pigs bits of pork such as might be found in garbage are reported in tabular and graphical form and discussed.

It was found that the meat and bone taken from carcasses of hogs killed before any manifestation of hog cholera other than elevation of temperature, at a time when they will pass inspection, will usually produce the disease when fed in small quantities to susceptible pigs. In hog-cholera infected carcasses that passed inspection the virus was not often killed in parts sold as fresh or refrigerated products. In sugar-cured hams the virus was killed in 12 out of 21 experimental cases.

"Measures to prevent hog-cholera infections due to feeding trimmings from market pork should include efforts to prevent marketing infected herds, efforts to prevent the sale of carcasses in products in which the virus is not killed, and efforts to acquaint swine breeders with the danger incident to feeding kitchen refuse. Farmers can avoid the danger mentioned by discontinuing the feeding of kitchen refuse, by placing all pork trimmings elsewhere than in the garbage pail, by thoroughly cooking all garbage before it is fed, or by immunizing their hogs. Men who collect and feed city garbage can avoid the danger by cooking all the material they feed or by immunizing their hogs."

The importance of severe interpretation of temperatures, symptoms, and lesions observed during inspection to indicate the proper treatment of any animals that might be infected without condemnation of appreciable numbers is indicated.

Transmission of piroplasmosis to three pigs by ingestion, Sparapani (Pathologica, 9 (1917), No. 196, pp. 21, 22; abs. in Trop. Vet. Bul., 5 (1917), No. 2, p. 90).—The author reports upon infection in pigs apparently brought about by ingestion of the flesh of infected sheep.

A note on dourine in the horse, H. T. PEASE (Agr. Jour. India, 12 (1917), No. 2, pp. 230-251, pls. 5, fig. 1).—A discussion of the disease and its treatment.

Abortive treatment of equine filariasis by the hypodermic injection of a permanganate of potassium solution, Monber (Rev. Gén. Méd. Vét., 22 (1913), No. 262, pp. 534-537; abs. in Vet. Rec., 27 (1915), No. 1394, p. 498).—The subcutaneous injection of 10 cc. of a 1 per cent solution of permanganate of potassium at six points in the pericicatricial zone has resulted in the cure of summer sores. The author is of the opinion that this treatment will give good results and that it may also be employed in filariasis of the tendons.

[Epizootic lymphangitis in France] (Bul. Soc. Cent. Méd. Vét., 92 (1916), Nos. 8, pp. 136-142, pl. 1; 11-12, pp. 144-155, pls. 4; 22, pp. 334-346; 24, pp. 385-388, 402-404; 93 (1917), Nos. 3-4, pp. 64-68; 6, pp. 99-109; 9-10, pp. 191-204; Rec. Méd. Vét., 92 (1916), No. 21, pp. 614-618; 93 (1917), No. 7-8, pp. 179-196, figs. 5).—Epizootic lymphangitis, a disease rarely seen in France before the war, has since been introduced with horses imported from northern Africa and is of quite frequent occurrence.

Several papers relating to the disease are presented as follows: Epizootic Lymphangitis in France: Diagnosis and Treatment, by J. Bridré; Treatment of Epizootic Lymphangitis—Trials with Galyl (Tetraoxydiphosphaminodiarsenobenzene), by Douville; Treatment of Epizootic Lymphangitis by Novarsenobenzol, by Velu; Note on the Treatment of Epizootic Lymphangitis by Potassium Iodid, by J. Cartier (E. S. R., 37, p. 377); Epizootic Lymphangitis in France—Its Treatment by the Chatelain Method and Its Prophylaxis, by E. Nicolas; Epizootic Lymphangitis in the Region of Mekinez, by Aubry; Epizootic Lymphangitis, by Velu; Observations Relative to the Incubation of Epizootic Lymphangitis, by Truche and Guignard; Epizootic Lymphangitis—Symptomatology, by Velu; Apropos of Epizootic Lymphangitis and Its Treatment, by Fayet; Epizootic Lymphangitis, by Charmoy; Notes on the Determination of the Incubation Period of Epizootic Lymphangitis in France, by Perrin; and The Curative Treatment of Epizootic Lymphangitis by Vaccine Therapy, by Velu.

Epizootic lymphangitis in France: Its diagnosis and treatment, J. Bridge (Vet. Jour., 78 (1917), No. 503, pp. 173-175).—This is a review of the article by Bridge above noted.

The author, together with Negri and Trouette, has obtained excellent results from the intravenous injection of arsenobenzol, but novarsenobenzol is deemed much more convenient to use and quite as effective. He recommends a dose of from 2 to 3 gm. in 20 cc. of distilled water, the injection to be made in the jugular vein.

"Stomatitis contagiosa" in horses, A. C. Burton (Vet. Jour., 73 (1917). No. 505, pp. 234-242, figs. 4).—The author has found that this disease of the horse is transmissible to man, both he and two assistants having contracted it. The disease in man was of short duration and mild, but very painful. The incubation period appeared to be from one to three days. Any immunity conferred by an attack appears to be short, reinfection having apparently taken place in less than two months.

The author has found frequent irrigation and cleansing of the mouth with potassium permanganate (0.5 oz. to 5 gal. of water) by means of a Vermorel sprayer carried on the back, the nozzle covered with a piece of rubber hose pipe, to be a very satisfactory means of treatment for army horses.

Note on an outbreak of contagious pneumonia in donkeys, R. Beanford (Agr. Jour. India, 12 (1917), No. 2, pp. 268-273, pls. 2).—This reports upon an outbreak of this disease among the young stock donkey jacks at the Government Cattle Farm, Hissar, on July 20, 1916.

Another cestode from the young cat, J. E. Ackert and A. A. Geant (Trans. Amer. Micros. Soc., 36 (1917), No. 2, pp. 93-96).—The authors find that the dog tapeworm (Tania pisiformis) may develop in the young cat (Felis domestica) and that evagination of Cysticercus pisiformis occurs in the duodenum of the domestic kitten.

Some of the infectious diseases of poultry, E. M. Pickens (Cornell Vet., 7 (1917), No. 3, pp. 151-184).—A systematic summary of information on the more important infectious diseases of poultry.

#### RURAL ENGINEERING.

Flow through sharp-edged V-notches or weirs, E. W. Doebler and F. H. RAYFIELD (Cornell Civ. Engin., 25 (1917), No. 8, pp. 389-397, figs. 7).—Experiments are reported on the flow of water through V-notch weirs to determine the experimental coefficient  $\mu$  in the formula

 $Q = \mu 8/15 \tan 1/2\alpha 2 \ gh^{6/2}$ 

for heads higher than those used in previous experiments by others. Four notches were studied. The smallest had the Cippoletti side slopes of one horizontal to four vertical, an angle of approximately 28°. The other three angles were 60, 90, and 120°. Heads were used up to 3 ft.

It was found that "the  $60^{\circ}$  notch has the lowest average coefficient, about 0.578, with the value for the  $90^{\circ}$  a very little higher, about 0.58. The average values of  $\mu$  for the 28 and 120° notches are respectively about 0.59 and 0.591, or about 2 per cent higher than the values for the intermediate notches. These averages are for the medium heads. . . . For all of the notches there is a rapid increase in the value of the coefficient at the high heads. This increase is, no doubt, partly due to the velocity in the channel of approach. . . .

"For those runs for which the velocity measurements were made, the mean heads were increased by their respective velocity heads and another coefficient computed. Considering these coefficients, there is still a marked increase in the value of the coefficients which tends to show that it is not entirely due to velocity. The nearness of the edges of a notch to the sides of the channel has an effect upon the coefficient."

Spray irrigation, G. H. Tolley (Water Conserv. and Irrig. Com., N. S. Wales, Bul. 1 (1917), pp. 32, figs. 36).—This pamphlet discusses the general principles of spray irrigation, and describes service tests of several different systems of spray irrigation.

Irrigation laws of the State of Washington, compiled by I. M. HOWELL (Olympia, Wash.: State, 1916, 2. ed., pp. 173).—The text of the laws is given.

Irrigation revenue report of the Bombay Presidency, excluding Sind, 1914-15 (Irrig. Rev. Rpt. Bombay Pres., 1914-15, pp. 49).—Data on expenditures and revenues for irrigation works in Bombay for the year 1914-15 are reported.

Annual report, Ministry of Public Works, Egypt, 1915-16, M. MacDonald (Ann. Rpt. Min. Pub. Works Egypt, 1915-16, pp. 87, pls. 9).—A large part of this report is devoted to drainage and irrigation projects in Egypt, especially as they are affected by the European war.

[Water analyses] (An. Min. Agr. Argentina, Secc. Geol., Mineral. y Min., 11 (1916), No. 4, pp. 53-63).—Analyses of 13 samples of 8 water supplies from 5 Provinces in Argentina showed 7 of the supplies to be potable. Analyses of 102 samples of 35 water supplies of 12 Provinces showed 19 samples potable.

Reaeration as a factor in the self-purification of streams, E. B. PHELPS (Jour. Indus. and Engin. Chem., 3 (1917), No. 4, pp. 403-405).—It is pointed out, on the basis of work by the U. S. Public Health Service, that "in the development of the maximum economic use of a stream, its capacity to dispose of

sewage and waste within any specified degree of depreciation or nuisance is a factor of first importance. This capacity is limited by stream conditions and is a function of the capacity for reaeration. For this reason the dilution unit is an improper one for a discussion of nuisance and self-purification, and results obtained upon one stream, expressed in such units, are not applicable to another. Reaeration is capable of experimental determination not only in single instances but in terms of general applicability. Its determination in such general terms involves laborious work of a hydraulic and analytical nature."

The javellization of water in the field, E. Arbinet (Rev. Hyg. et Pol. Sanit., 39 (1917), No. 2, pp. 98-104, figs. 3).—This process is described.

A comparison of the activated sludge and the Imhoff tank trickling filter processes of sewage treatment, H. P. Eddy (Jour. West. Soc. Engin., 21 (1916), No. 10, pp. 816-852, figs. 11; Surveyor, 51 (1917), No. 1317, pp. 370-372, figs. 2).— From a comparison of the two processes of sewage treatment it is concluded that at the present time "the Imhoff tank trickling filter process is a less expensive means of oxidizing the organic matter of sewage wastes than the activated sludge process, where oxidation alone is considered. If the areas of land required for isolation, the loss of head in the plant, the danger of objectionable odors and of the fly annoyance, and other disadvantages of the trickling filter process are of marked importance in any specific case, the balance may be decidedly in favor of the activated sludge process, even in its present state of development. . . . Further attention should be given to improvement in the design and operation of the oldest processes of sewage treatment."

Marked advance in treating sewage from packing houses, G. B. ZIMMELE (Engin. News-Rec., 78 (1917), No. 9, pp. 436, 437, fig. 1).—Experiments conducted at Forth Worth, Tex., on the treatment of packing-house waste by means of a small activated sludge plant showed that this sewage can be successfully handled by the activated sludge treatment. With reference to the fertilizing value of the sludge it was found that "the addition of the acid holds the ammonia—contrary to the effect of adding lime. Second, the availability of the nitrogen is increased. By the neutral permanganate method, blood contains about 90 per cent available nitrogen, but this treated sludge contains about 93.5 per cent available nitrogen."

An experimental test of the relation of sewage disposal to the spread of pellagra, J. F. Siler, P. E. Garrison, and W. J. MacNeal (Arch. Int. Med., 19 (1917), No. 5, pt. 1, pp. 683-694, Ags. 2).—An account is given of an experiment conducted in a small milling community in South Carolina which had long been a conspicuous endemic center of pellagra. In the fall of 1913 the installation of a water carriage sewerage system was begun and a few houses were equipped with water and fly tight pail closets. As far as possible all privies in the community were made fly and water tight regardless of their character.

"The diminution in new cases of pellagra in this community from 30 in 1913 to 18 in 1914, eight in 1915, and two in 1916 has been very remarkable, and the obvious cause of this improvement would appear to be the intentional experimental factor, namely, the installation of the sewerage system. . . . The installation of sanitary systems of sewage disposal is recommended as a measure for the restriction of the spread of pellagra in the general population."

Rational and economic sanitary treatment of human wastes, F. Garrigou (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 17. pp. 649-651; abs. in Chem. Abs., 10 (1916), No. 19, p. 2490; Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 7. pp. 947, 948).—A method of sewage treatment considered as an economic war measure in France is described.

The liquid and solid constituents are separated by sedimentation and decantation. The treatment of the liquid portion is based on the double decomposition

of calcium sulphate in the presence of ammonium carbonate, giving calcium carbonate and amonium sulphate. The calcium carbonate settles out and the liquid containing ammonium sulphate is concentrated until the crystals separate. The precipitated calcium carbonate contains much organic matter rich in nitrogen. The solid matter from the decantation process is filter pressed and then autoclaved for 15 minutes at 140 to 150° C. The vapors from the autoclave are condensed to recover the ammonia salts in them, and the solids remaining in the autoclave are dried for fertilizer. This process, it is stated, requires only a simple apparatus and cheap chemicals and is considered to be adapted for use on farms and in rural communities of France, as well as in larger towns, for the production of fertilizer from sewage.

Rural sanitation (Cal. Bd. Health Mo. Bul., 12 (1916), No. 2, pp. 74-81; abs. in Chem. Abs., 10 (1916), No. 21, p. 2780).—This article outlines the public health methods of the California State Board of Health and describes common unhealthful conditions, including sewage entering streams, contaminated wells and water supplies, carelessness in producing and handling milk, manure piles, fly and mosquito breeding places, and insanitary privies. A form of notice to abate nuisances issued by the board is included.

Fifth annual report of the county highway commissioner of Milwaukee County, Wis., 1916, H. J. Kuelling (Ann. Rpt. Co. Highway Comr., Milwaukee Co., Wis., 5 (1916), pp. 93, figs. 28).—This is a statement of the work and expenditures of the office of the highway commissioner of Milwaukee County, Wis., on highway construction, maintenance, and repair for 1916.

Road problems in the Ozarks, E. G. HARRIS (Bul. School Mines and Metallurg., Univ. Missouri, 9 (1917), No. 1, pp. 23, figs. 6).—This bulletin is a discussion of the road problems encountered in the average sparsely settled, rugged portion of the Ozark uplift, embracing about one-fourth of the area of Missouri. It is stated that in this region the present bad location of many of the roads constitutes the chief reason why improvement is impossible or possible only at great and continuous expense.

A list of references, compiled by H. L. Wheeler, on the construction and maintenance of rural roads is included.

Report of the fourth annual road drag competition, J. Kuehne and H. W. Heffle (Saskatchewan Highway Comrs., Rpt. Road Drag Compet., 4 (1916), pp. 22, flgs. 8).—An outline is given of the procedure and results of a road dragging competition in the Province of Saskatchewan lasting through the summer of 1916.

Methods of determining the road making qualities of deposits of stone and gravel, L. Reinecke (Good Roads, 51 (1917), No. 20, pp. 293-297, figs. 9).—This is an outline of the methods used by the department of mines of Canada in arriving at the relative values of deposits of stone and gravel available for road construction.

"In order to determine the road making values of the rocks in a certain district, they are first divided into formations and then into rock types. Their average values and the variation in strength and cementing value of each type are obtained by laboratory tests on a number of samples, and the results thus obtained are compared with actual service tests in the roads wherever possible. Laboratory studies with the microscope and by chemical analyses are then undertaken to discover the cause of such variations in order to furnish data which will enable the field man to distinguish a good stone from a poor one in the outcrop.

"With a working knowledge of the strength of the bedrock in a district, an attempt is made to devise a classification of the kinds of bowlders in the field

stone deposits in such a way that their composition expressed in percentages of durable, intermediate, and soft bowlders will bear a direct relation to their percentage of wear as determined in the laboratory and to their durability under traffic conditions. The pebbles in the gravels of the district are classified in a manner that will bring about the same result. The impurities present and the texture or grading of the gravels are studied in order to furnish advance data as to their probable value in concrete and sheet-asphalt work."

The arrangement of rectangular dairy barns, R. S. Hulce and W. B. Nevens (Illinois Sta. Circ. 199 (1917), pp. 3-30, figs. 23).—This circular enumerates the factors to be considered in the location, lighting, ventilation, and general arrangement of rectangular dairy barns and gives information regarding principles of construction.

Wooden silos used in Nebraska, L. W. Chase and I. D. Wood (*Univ. Nebr.*, Col. Agr. Ext. Bul. 40 (1917), pp. 16, figs. 11).—This bulletin relates especially to the construction of wooden silos under Nebraska conditions and includes diagrammatic illustrations and bills of materials.

The principles of poultry house construction with general and detailed plans, F. C. Elford (Canada Expt. Farms Bul. 87 (1916), pp. 55, figs. 55).—This bulletin enumerates the principles of construction and gives general and detailed plans and specifications for farm and commercial poultry houses, including their interior arrangement and equipment.

Better conveniences for rural schools, L. E. Scott (Wis. Farmers' Insts. Bul. 30 (1916), pp. 48-55, figs. 7).—Sanitary conditions and conveniences for rural schools, especially with reference to lighting, heating, ventilation, water supply, and sewage disposal, are discussed.

#### RURAL ECONOMICS.

The marketing of Kansas butter, T. Macklin (Kansas Sta. Bul. 216 (1917), pp. 3-79, figs. 42).—This investigation was made for the purpose of determining the methods, processes, and costs of marketing butter made both on farms and in creameries of the State.

It is concluded that "dairy farming in Kansas has been and continues to be a side line on the average farm. Experience with whole-milk creameries, local private creameries, and skimming-station centralizers proved that they were not adapted to Kansas conditions, and led to the establishment of cream-station direct-shipper centralizers, which are well adapted to the conditions of Kansas dairy farming. Farm butter making has rapidly declined in Kansas owing to the rapid increase in the efficiency of creameries. . . . The average farmer does not live close enough to favorable markets to make and market butter profitably, except in so far as the stores follow the practice of paying the same price for both good and poor butter. . . .

"Kansas has 78 creameries. Forty-one are centralizers, which make more than 95 per cent of the creamery butter of the State. . . . Centralizers are necessary because there is only one creamery for each 1,053 square miles, and the average farmer lives 19 miles from a creamery. . . .

"The prices paid for delivered butter fat by centralizers averaged above Elgin prices, and according to prevailing economic conditions, appear to be fair. The fact that butter-fat prices in Kansas are somewhat lower than in some other States is because farmers choose to sell four-fifths of their butter fat through cream stations rather than to deliver the cream at their own expense.

"More and better dairy cows would have the effect of reducing the cost of getting butter fat to the creameries, of lowering the cost of making and marketing butter by the creameries, and would result in higher net prices and greater profits to the farmer."

The wheat question, M. Perchot (Vie Agr. et Rurale, 7 (1917), No. 25, pp. 433-440).—This report discusses the stock of wheat on hand, the consumption requirements, the influence of fixing of the price on production, and methods of restricting consumption.

Observations on the recent agricultural inquiry in California, T. F. Hunt (California Sta. [Pub., 1917], pp. 20).—The author discusses the findings of the committee on resources and food supply of the State council of defense. He recommends that the council devise means to bring city labor resources in touch with country needs, to organize tractor garages, to urge city capital and people to engage in the production of food, to promote plans of meeting the livestock situation, to urge conservation of food and elimination of waste through organizations of women, and to assure the producer of high prices.

The great war: Its lessons and its warnings, J. Collings (London: The Rural World Publishing Co. [1917], pp. 113, pls. 2).—The author deals in a general way with the deficiencies of English agriculture in meeting national demands in time of war. A material reduction of the acreage in grass, more intensive cultivation and division of agricultural lands, reclamation of waste lands, and state aid to bring about reform are lessons emphasized.

A comparison of the systems of agriculture on the Continent, where intensified farming predominates, with that in England, is carried through the book.

The land and the Empire, C. H. Turnor (London: John Murray, 1917, pp. 144, figs. 28).—The author treats of errors in the policy of English agriculture in the past, which permitted a decrease in rural population as well as agricultural production. Occupying ownership, more practical education, betterment of labor conditions, and a more efficiently organized agricultural industry are urged as essentials in the solution of the problem.

The English land system, J. A. R. Marriott (London: John Murray, 1914, pp. X+168).—The author traces the development of the English land system from the viewpoint of social and economic history. Its origin in the manorial system, the effect of the Black Death and peasant revolts, the agrarian revolutions of the sixteenth and eighteenth centuries, resulting in large estates and decay of yeomanry, and the causes and outcome of the periods of plenty, as well as depression, of the nineteenth centry agriculture are noted with some detail.

The concluding chapter deals with the land problem to-day, reviewing such suggested solutions as land nationalization, a land commission to settle on such questions as "fair rent" and "security of tenure," and the increase in small holdings through a system of land purchase involving State assistance.

Land improvement in the Province of the Rhine, Heimerle (Landw. Jahrb., 48 (1915), No. 2, pp. 171-277, pl. 1).—This is a survey of improvements made in Rhenish irrigation and drainage conditions during the past century. Technical, legal, and economic phases are studied, including soil and climatic conditions, drainage and drainage regulations, financial aid, economy of improvement and production increase, and general effect on commerce and population.

Madras agriculture.—A brief survey (Madras: Dir. Agr. [1916], pp. 87).—The introduction briefly reviews conditions pertaining to general land economics. Following data of a general nature concerning the variety of crops produced, with the acreage distribution, each crop is considered separately in reference to its locality, manner of cultivation, improvement, and comparative quality. Statistical tables are presented for the principal commercial crops showing the quantity, value, months when available for export, and distribution of foreign trade.

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt., 3 (1917), Nos. 6, pp. 45-56, figs. 2; 7, pp. 57-68, fig. 1).—These two numbers contain the usual data

regarding the estimated crop conditions of the more important crops, the estimated farm value of important products, and range of prices of these products at important markets.

In the first number special data are also given regarding the United States summary of farm prices, the monthly composite crop-condition estimates, index figures of crop prices, ten-year averages of conditions of crops, the estimated production in 1916 of the different varieties of wheat in the three spring-wheat States, special reports regarding Florida and California crops, the commercial production of strawberries, Bermuda onions, and early Irish potatoes, the date of harvesting watermelons, fertilizer used on cotton in 1917, the peanut acreage, the world's production of cereals by five-year periods, and the estimated acreage of hay. The number also includeds a reprint of a special article on the uses made of the corn crop (E. S. R., 28, p. 595), the length of cotton lint for the crops of 1916 and 1915, the international exports of wheat, and the monthly world export of wheat and flour for the five years 1910 to 1914, inclusive.

The second number contains special reports relating to honey yields and prospects, the commercial cherry crop, area planted to sugar beets, prices to producers of cotton and cotton seed, the production and acreage of grain sorghums, a special bean report, potato forecasts by harvest periods, data relating to prices indicating the increase in average of prices, and index figures of crop prices, commercial acreage and production of cantaloups, and acreage and conditions of tobacco by types and districts, together with data relating to the acreage devoted to onlons, etc.

# AGRICULTURAL EDUCATION.

Proceedings of the thirtieth annual convention of the Association of American Agricultural Colleges and Experiment Stations, edited by J. L. Hills (Proc. Assoc. Amer. Agr. Cols. and Expt. Stas., 30 (1916), pp. 363, figs. 3).—This is a detailed report on the proceedings, including the papers submitted and discussions thereof, of the meeting of the association held at Washington, D. C., November 15-17, 1916.

In addition to the papers and reports previously noted (E. S. R., 35, p. 700), the proceedings also contain the following: Proposed Legislation to Establish Engineering Experiment Stations, by A. Marston (pp. 26-33); Scientific Management as Applied to the Farm, Home, and Manufacturing Plants, by C. R. Jones (pp. 108-115); Report of Joint Standing Committee on Projects and Correlation of Research (p. 133); Report of the Executive Committee (pp. 140-142); The Reserve Officers' Training Corps, Historical Statement, by W. O. Thompson (pp. 142-144); Problems and Opportunities Presented by the New Federal Army Reserve Law, by G. P. Benton (pp. 145-150); The Reserve Officers' Training Corps, by W. M. Riggs (pp. 150-152); Report of the Secretary, A. A. Potter, of the Engineering Division of the Section on College Work and Administration, setting forth in brief the history of the campaign in connection with the engineering experiment station bill (pp. 198,199); The Appropriate Field in Engineering Extension for the Separate Land-grant College and the State University, by D. W. Spence (pp. 200-202); and by C. H. Benjamin (p. 207); Mechanic Arts of Sub-collegiate Grade in Land-grant Colleges, by C. E. Hewitt (pp. 212-215); and by W. N. Gladson (pp. 215-218); The Field of Engineering Experimentation, by R. L. Sackett (pp. 224-229), followed by a review by A. P. Davis of some of the possibilities or facilities of the U. S. Reclamation Service along these lines; Control of Engineering Experimentation in the Land-grant Colleges, by H. S. Boardman (pp. 232-234); The Cooperation of Teachers of Agriculture and Engineering in the Agricultural and Engineering Curriculum, by R. J. Aley (pp. 241-245); The Status of the Land-grant College as Outlined in Reports of Surveys Recently Made by the U. S. Bureau of Education, by S. P. Capen (pp. 246-252); and Economic Factors to Be Considered in Connection with the Project for Extension Work among Farm Women, by E. Merritt (pp. 339-346).

Short courses in agriculture and home economics, W. J. Reid et al. (Agr. Gaz. Canada, 4 (1917), No. 5, pp. 363-386, figs. 6).—This is a symposium on short courses in argiculture and home economics held in the past winter in the various Provinces of Canada. Approximately 500 short courses were held, with an aggregate attendance of 175,000 persons. Upwards of \$160,000 was appropriated for 1916-17 for instruction and demonstration and women's work.

Household science in normal schools, H. V. B. Bridges et al. (Agr. Gaz. Canada, 4 (1917), No. 5, pp. 400-407, figs. 2).—This is an account of the instruction in household science given in the normal schools of Ontario, Saskatchewan, and Alberta.

[Agricultural and home economics instruction in the public schools of New Hampshire], G. H. WHITCHER and F. H. DAMON (N. H. Dept. Pub. Instr., Inst. Circ., 1915-16, Nos. 58, pp. 11; 59, pp. 22; 1916-17, No. 72, pp. 11, figs. 6).—These circulars deal respectively with methods of cooking meat and diets for invalids, including suggestions as to methods of teaching these subjects, and a description of a poultry plant made by the boys of the Dover (N. H.) high school.

Some exercises in farm handicraft for rural schools, H. O. Sampson (U. S. Dept. Agr. Bul. 527 (1917), pp. 38, figs. 41).—This bulletin is intended primarily for rural school teachers and for pupils of the seventh and eighth grades. It contains outlines of 25 exercises in the making of useful articles for the school, farm, and home. The exercises have practical application in the agricultural work of the school and also to the various club projects in agriculture.

Working drawings and photographs showing the construction of farm buildings for use in manual training schools (Nat. Lumber Manfrs. Assoc., Trade Ext. Dept., Ed. Ser. [Pub.] 3 (1917), pp. 15, figs. 16).—This includes a corn crib, implement shed, granary, dairy house, poultry house, garage, and general-purpose barn.

#### MISCELLANEOUS.

Annual Report of Florida Station, 1916 (Florida Sta. Rpt. 1916, pp. 118+IV, figs. 22).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1916, a list of the publications of the year, a general review of the work of the station during the year, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Thirty-ninth Annual Report of North Carolina Station, 1916 (North Carolina Sta. Rpt. 1916, pp. 207, pl. 1, figs. 56).—This contains the organization list, a report of the director and heads of departments, a financial statement for the fiscal year ended June 30, 1916, and reprints of Bulletins 232–236. The experimental work reported is for the most part abstracted elsewhere in this issue.

Barn and field experiments in 1916, C. D. Woods (Maine Sta. Bul. 260 (1917), pp. 85-120).—These experiments are presented in 13 articles abstracted elsewhere in this issue.

Monthly Bulletin of the Western Washington Substation (Washington Sta., West. Wash. Sta. Mo. Bul., 5 (1917), No. 4, pp. 45-60, figs. 7).—This number contains brief articles on the following subjects: Hay Caps, by H. L. Blanchard; Blanching, Harvesting, and Marketing of Celery, by J. L. Stahl; Summer Spraying for Garden Pests, by A. Frank; Summer Feeding, by G. R. Shoup; Poultry Accounts, by Mrs. G. R. Shoup; and Concerning Moles, by T. H. Scheffer.

Alabama College and Station.—R. U. Blasingame, professor of agricultural engineering and agricultural engineer, resigned November 1 to become associate professor of farm mechanics in the Pennsylvania College.

Arizona University and Station.—Recent appointments to the board of regents include Dr. William V. Whitmore, of Tucson, formerly treasurer of the board, as president and chancellor; John P. Orme, of Phoenix; E. Titcomb, of Nogales; Dr. John W. Flinn, of Prescott; and Captain J. P. Hodgson, of Bisbee. State appropriations for the college and station have been made of \$72,569.59 for 1917-18, and \$75,164.15 for 1918-19.

California University.—The dedication of Hilgard Hall took place October 13. The new building is an elaborate 4-story structure, of reinforced concrete, 60 by 300 ft., costing with equipment about \$370,000 and constituting the second of the three buildings which will complete the agricultural quadrangle. It will serve as the headquarters of the college of agriculture, housing the departments of agronomy, citriculture, forestry, genetics, pomology, soil technology, and viticulture. A feature of the dedication exercises was a series of popular conferences on subjects connected with the work of each of these departments. A number of addresses commemorating the life and activities of Dr. Hilgard were also given, including one by Dean Hunt entitled Carrying Hilgard's Work Forward.

Connecticut State Station.—W. C. Pelton, county agent for Sussex County, Del., has succeeded Howard F. Huber as vegetable expert.

Illinois University and Station.—Warren R. Schoonover, instructor in soil biology in the department of agronomy and assistant biologist in the station, has enlisted in the gas defense service of the Sanitary Corps, U. S. Army.

Purdue University and Station.—W. J. Jones, Jr., professor of agricultural chemistry and State chemist for the past 10 years, died August 31, aged 46 years. He was a graduate of the university in 1891, and received the degree of M. S. in 1892 and that of agricultural chemist in 1899. His entire career was spent at the university and dealt especially with control work. He had long been a prominent figure in the Association of Official Agricultural Chemists and was widely known among fertilizer and feeding stuff control officials throughout the country.

Laurenz Green, chief in pomology in the Iowa Station, has been appointed head of the horticultural department. Harry M. Weeter has been appointed associate professor of dairy bacteriology and associate dairy bacteriologist, vice H. B. Switzer, who has accepted a position with the U. S. Department of Agriculture under the Food and Drugs Act with headquarters at Chicago.

Kansas College.—President Henry J. Waters has resigned to become managing editor of the weekly Kansas City Star.

Louisiana Stations.—Nicholas Kozeloff, Ph. D. (Rutgers, 1917), has been appointed bacteriologist of the Sugar Station, vice W. L. Owen, whose resignation has been previously noted.

Vermont University.—President G. P. Benton has been given a year's leave of absence for service with the National War Council in France. Dean G. H. Perkins, of the College of Arts and Sciences, has been designated acting president.

Editorial notes: Attendance at the agricultural colleges as affected by the war. Recent work in agricultural science. Notes. SUBJECT LIST OF ABSTRACTS.	Page. 701 709 797
AGRICULTURAL CHEMISTRY—AGROTECHNY.	
Chemical studies in making alfalfa silage, Swanson and Tague	709
The isolation of parahydroxybenzoic actd from soil, Walters	709 710
Occurrence of raffinose in the seed of the jute plant, Annett	710 710
The effects of exposure on some fluid hitumens. Reeve and Lewis	711 711
Importance of uniform culture media in examination of disinfectants, Wright. A simple ultramicroscope, Kiplinger.  Sampling tubes for manure, alfalfa, or other organic materials, Shamel	711 711
A sampling press, Clark	711 711
Simple apparatus for hydrogen sulphid precipitation under pressure, Fuller  Ashing organic materials for determination of potassium, Blumenthal et al  A revision of the cobalti-nitrite method for potash, Haff and Schwartz	$712 \\ 712$
A revision of the cobalti-nitrite method for potash, Haff and Schwartz.  The solubility of calcium phosphates in citric acid, Ramsay.  A method for the destruction of organic matter, Gautier and Clausmann	$712 \\ 713$
Iodometric determination of chlorin in chlorids, Torossian	713 714
A new test for chlorin in drinking water, Wallis.  The chemical examination of potable waters.—I, Organic matter, Kolthoff	714 714
1	

	Page.
A new method for the determination of aldehyde sugars, Bougault	714
The acid content of fruits Bigelow and Dunbar	714
Sources and composition of commercial invert sugar strups, Jordan and Chesley	715
Relative value of different weights of tin coating on canned food containers	715
War food, Handy	715
The evaporation of fruits and vegetables, Caldwell	715
A new method for the preparation of pectin, Caldwell	715
Carbonation studies.—1, Mechanical stirrer for carbonation, Patten and Mains.	716
Vinegar investigation.—Changes that cider undergoes, Hartman and Tolman.  Preserving fish for domestic use, Moore	716
A practical small smokehouse for fish	716
A practical small smokehouse for non-	120
METEOROLOGY.	
New methods of weather prediction, Voss	716
Factors influencing condensation of aqueous vapor in the atmosphere, Masini.	716
Relation between forests and atmospheric and soil moisture in India, Hill	716
Rainfall and gunfire. Angot	717
Correlation between atmospheric phenomena and the yield of crops	717
Phenological observations in the British Islands, Clark and Adames	717
Climatological studies.—German East Africa, Lyons	717
SOILS-FERTILIZERS.	
mi 'l Latin shaded by the all message method Marron	717
The soil solution obtained by the oil pressure method, Morgan  Is the humus content of the soil a guide to fertility? Carr	718
Effect of addition of organic matter on development of soil acidity, Miller	718
Is there any fungus flora of the soil? Waksman	718
Biological variations in soil plats, Allison and Coleman	719
The effect of sterilization of soils by heat and antiseptics, Koch	719
Some effects of auximones on the growth of Lemna minor, Bottomley	719
Du Page County Soils, Hopkins, Mosier, Van Alstine, and Garrett	720
Soil survey of Dickey County, N. Dak., Bushnell et al	720
Sand devastation, Collins.	720
The improvement of the poor soils and run-down soils of New Jersey, Dickey.	720
Manure and fertilizers for peat soil poor in nitrogen, von Feilitzen	720 721
American sources of nitrogen, Norton.  The production of sulphate of ammonia for 1915–16.	721
Adsorption of ammonium sulphate by soils and quartz sand, Wolkoff	721
Saltpeter: Its origin and extraction in India, Hutchinson	722
Potash from incinerator ash of the Northwest, Thing	722
Tetraphosphate, Vinassa	722
Tetraphosphate, Vinassa	723
The liming of limy lands, Rosenfeld	723
Rules and regulations for the enforcement of the lime-barrel act, Stratton	723
The fertilizer value of city wastes II, Garbage tankage, Schroeder	723
Turf bedding and compost, Vikhlaev	$723 \\ 724$
Artificial fertilizers, their present use and future prospects, Russell	724
The American fertilizer handbook. Commercial fertilizers, Jones, jr., et al.	724
Results of fertilizer inspection, spring season 1917, Patten	724
AGRICULTURAL BOTANY.	
Metroclinic inheritance in Enothera reynoldsii, La Rue and Bartlett	724
A new type of non-Mendelian variation in plants, Ikeno	725
The relation between evaporation and plant succession in a given area, Gates	725 725
Adaptations of vegetation to climate, Massart	720
Duration of leaves in evergreens, Pease	726
The reaction of plant protoplasm, Haas.	726
The mode of action of plant peroxidases. Reed.	726
Action of potassium permanganate with peroxidases, Bunzel and Hasselbring.	726
The response of plants to illuminating gas, Doubt	726
Damage to greenhouse crops and soil from escaping illuminating gas, Stone	727
Leaf nectaries of Gossypium, Reed	727
On the formation of neglules in the cortex of Hence brasiliensis Bruce	727

	Page.
Preliminary observations on distribution of certain hymenomycetes, Peyronel. Studies in the physiology of the fungi, III, Zeller	727 727 728 728
FIELD CROPS.	
General agriculture, Diffloth. Agronomical investigatoins [at Guam Experiment Station, 1916], Hartenbower. [Report on field crops work at the Missouri Experiment Station]. [Field crops], Watts. # EXPERIMENT STATION RECORD.

Vol. 37.

**DECEMBER**, 1917.

No. 8.

The beginning of the new academic year this fall was awaited by most institutions devoted to higher education with unusual uncertainty and apprehension. The declaration of a state of war in April had profoundly affected these institutions almost immediately. Attendance, which in most colleges and universities had been steadily rising from year to year, was suddenly depleted as the call came for one form or another of National service, in some places the campus emptying almost over night. Some institutions closed their doors early in May, and in others work went on under greatly altered conditions. Commencements were quite generally omitted or curtailed, and July 1 found the undergraduates nearly as widely scattered as the alumni, with every indication that a considerable percentage would never return and that entering classes might also be much smaller than for many years.

The seriousness of such an outcome, not merely to the institutions but to the ultimate welfare of the Nation, was quite generally foreseen, but there was also more or less uncertainty as to the duty of the institutions and the individual students under the emergency conditions. It was apparent that the Nation had immediate need of thousands of its young men, many for military service and many along other lines; that the shortage of labor on the farms, in the factories, and elsewhere was enormous; and it was inevitable that such factors would influence many a boy against beginning or continuing a college course which would even temporarily keep him from active participation in the strenuous work of the conflict itself. On the other hand it was also seen that the war had vastly increased the need for trained men and that the supply of these men could not safely be allowed to fail.

In response to an inquiry from the Secretary of the Interior as to the duty of the colleges and technical schools during the war, the situation was admirably stated by President Wilson in a letter of July 20, 1917, as follows: "The question which you have brought to my attention is of the very greatest moment. It would, as you suggest, seriously impair America's prospects of success in this war if the supply of highly trained men were unnecessarily diminished.

There will be need for a larger number of persons expert in the various fields of applied science than ever before. Such persons will be needed both during the war and after its close. I therefore have no hesitation in urging colleges and technical schools to endeavor to maintain their courses as far as possible on the usual basis. There will be many young men from these institutions who will serve in the armed forces of the country. Those who fall below the age of selective conscription and who do not enlist may feel that by pursuing their courses with earnestness and diligence they also are preparing themselves for valuable service to the Nation. I would particularly urge upon the young people who are leaving our high schools that as many of them as can do so avail themselves this year of the opportunities offered by the colleges and technical schools, to the end that the country may not lack an adequate supply of trained men and women."

Subsequently, under date of November 23, 1917, a letter of much the same tenor from the Secretary of War to the chairman of the special committee on universities and colleges of the Council of National Defense was made public, which reads as follows: "The successful outcome of the war is so dependent upon the applications of science that the United States can ill afford at this time to risk any diminution of this supply of technically trained men. Such diminution we must in part suffer by reason of the fact that class exemptions in the execution of the selective service law are prejudicial to its general success, but I have constantly in mind the fact that the Government service will demand more and more scientifically trained men, and so I hope those who are in charge of scientific institutions will impress upon the young men the importance and desirability of their continuing their studies except to the extent that they are necessarily interrupted by a mandatory call under the provisions of the selective conscription law."

It will be noted that in both these statements particular stress is laid upon the need for men trained in applied science. In this group would be included, of course, the graduates of the agricultural colleges. In view of the important and unique functions which these institutions have to fulfill, and the realization that in some ways the conditions regarding their prospective attendance differed from those in other institutions, it was deemed of general interest to attempt to ascertain, after their reopening, how they had fared as regards enrollment. Information was, therefore, sought by the States Relations Service as to the initial registration of college students in agriculture this fall as compared with the previous year, and also as to how any changes in the enrollment in agriculture compared with other kinds of education. A general survey of the existing situation, rather than a collection of statistical data, was

intended, although numerical data were gathered so far as readily available. Opinions were also sought as to any obvious changes in the character of the enrollment, as in age of students, relative proportion from farms and cities, proportion of men and women, purpose in coming to college, selection of courses of study, and similar matters, and especially as to the apparent underlying causes for such changes as were noted.

Information was supplied on some of these points by 48 institutions, located in 42 States and Hawaii. The reports covered nearly all sections of the country, and it is believed are representative of the situation as a whole. Although the inquiry necessarily reached the presidents, deans, and registrars at an exceptionally busy period, in most cases very complete data were furnished by these officials, through whose courteous response the preparation of this summary is made possible.

The data available indicate very clearly that a considerable shrinkage in total student enrollment in higher education occurred quite generally throughout the country. For the land-grant institutions this apparently averaged slightly over 20 per cent. In no institution reporting was there any considerable gain, although in such widely separated States as North Dakota, Oregon, South Carolina, Texas, and Virginia, substantially the registration of the previous year was maintained. On the other hand, decreases of nearly 50 per cent were encountered in a large university of the Middle West and a small southwestern college. The average percentage of falling off for the group, however, was probably less than for many of the oldest and best known universities of the country, press reports announcing, for instance, decreases of about 40 per cent for Harvard, Yale, and Princeton.

As regards students in agriculture, the showing is considerably less favorable than for total enrollment. The average decrease for the institutions reporting was slightly over 30 per cent and in numerous cases exceeded 50 per cent. Some sectional variation was noticeable, several southeastern colleges maintaining their previous registration and others falling only slightly below it, while losses were exceptionally heavy in the Southwest and in the Middle West.

On the other hand, the average decrease in the mechanic arts was approximately only 15 per cent and did not exceed 36 per cent for any institution. Four colleges reported gains of from 11 to 14 per cent, and in eight others the loss was under 10 per cent. These comparatively small losses were apparently typical of the technical schools in general, the Massachusetts Institute of Technology, for instance, reporting a loss of 18 per cent and the Carnegie Institute of Technology one of 16 per cent.

It seems probable that the explanation for the great difference noted between agriculture and the mechanic arts needs be sought in several directions. The unprecedented shortage of farm labor and the emphasis placed on an adequate food supply as a war measure doubtless kept many a boy on the farm, where his services could ill be spared, and the fact that his college training was unfinished, or even not begun, seemed much less important than his immediate availability as a dependable labor unit. More of the mechanic arts students, however, are recruited from the towns and cities, and while the labor shortage afforded them unusual opportunities for lucrative employment along industrial lines, they were often freer to follow their inclinations and the temptation to drop out of college was less keen because the opportunities were less closely associated with their chosen professional work. The enormous demand for trained engineers, chemists, and similar technically educated men was a strong inducement to boys graduating from high school to go to college and prepare themselves along these lines, while the limited field for halftrained workers discouraged the abandonment of the courses already begun. In short the feeling, formerly well-nigh universal and never entirely overcome, that thorough training is a necessity in the mechanic arts but less essential in agriculture, very likely explains some of the differences in relative enrollment.

In general the remaining courses offered by the land-grant institutions showed losses greater than for the mechanic arts and smaller than for agriculture, but there were many local variations. Even the enrollment of women, whether in home economics courses or in colleges of liberal arts, showed a considerable decrease in many cases, though this as a rule was less than the diminution of men and in some cases there were slight gains. The number of women students in agriculture continued to be too small for safe generalizations, but gives little indication of any increasing trend in this direction.

Analysis of the registration by classes revealed heavy losses at every stage. As would be expected, the senior class was largely effected, decreases of from 40 to 60 per cent being not uncommon. Obviously this class contains more men of draft age than those below it, and in many institutions men with longer military training, hence the call to the colors has been specially strong. Senior students also possess the maximum of specialized agricultural training and their services are in great demand along these lines. While it is desirable that the seniors should return and complete their work, particularly since these students include some of the most mature and otherwise promising material for development as teachers, investigators, and extension workers, withdrawals seem in many instances inevitable under the existing conditions.

The depletion of the junior and sophomore ranks was found to be somewhat smaller in most institutions. The reasons actuating withdrawals were substantially the same as with seniors, but applied with decreasing force, so that it seems probable that losses will be relatively somewhat less numerous and less detrimental.

The entering classes, however, present a special problem for consideration. Before the war steadily increasing numbers of freshmen, in many cases taxing the capacity of the college, had been the rule, but this fall thirty-six institutions reported losses ranging from 8 to 60 per cent. The Texas College, to be sure, reported an increase of over 12 per cent, resulting in the largest class in its history, and four others showed smaller gains, but the average for the entire group is a loss of about 25 per cent.

This percentage is, of course, smaller than for the entire enrollment in the colleges of agriculture, but it is none the less disquieting. In eighteen institutions it ranged from 30 to 40 per cent, whereas in mechanic arts courses only one institution showed an entering class more than 25 per cent below that for the previous year, while in fourteen others the losses were under 10 per cent and six showed gains of from 78 to 165 per cent. The percentage loss in freshman agricultural students was also considerably greater in the majority of institutions than for most other courses, although in some cases the falling off among male students in liberal arts was also large.

Expressed not in percentages, but in actual numbers, the data are even more striking. For the institutions available the freshmen aggregated in 1916, 4,630, and in 1917, only 3,463. This means a decrease of 1,167 freshmen students in agriculture in the 41 States reporting this item.

So heavy a decrease in this group, especially if it portends similar small entering classes for several years to come, must be regarded as unfortunate. It is unlikely that many of the boys who are thus foregoing a college course are of draft age or that any considerable proportion is engaged in military service. It seems probable that most of them have stayed on the farm, where they have indeed rendered sorely needed assistance, but it may be at a cost of an ultimate serious loss of hundreds of trained men to the Nation. The fact that the full extent of this loss will not be evident for several years only emphasizes how difficult it will be to remedy it when it becomes apparent. It would seem that special efforts should be made by the colleges to enlighten prospective students as to the unusual opportunities for trained agricultural workers within the next few years. Some institutions have already begun work along this line.

The group of students most seriously affected of all is, as would be expected, that of graduate students. The data reported as to these students are somewhat less complete than for undergraduates, since in the larger universities they are quite often enrolled in general graduate schools instead of in the colleges of agriculture. For eighteen institutions reporting graduate students in agriculture in 1916, the aggregate enrollment has dropped from 410 to 202, or over 50 per cent. This condition will doubtless continue or perhaps be aggravated, since most of these students are of draft age and openings for active employment were never more numerous.

Another phase of the matter which needs consideration is the subsequent dropping out of the students who have returned to college. Hardly an issue of a college paper has appeared this fall without items announcing such withdrawals. Many of these are for military service, but others are often for less vital reasons and should be kept at a minimum. As the committee on instruction in agriculture pointed out in its recent report to the Association of American Agricultural Colleges and Experiment Stations, "in this country and abroad, agriculture is now recognized to be of importance second only to the military service, even under war conditions. On this account there is a heavier burden of responsibility upon the young men of our agricultural colleges students and graduates alikewho have not been called to military service. The burden is greater not only because of the demand for greater production, but also because of the smaller number of young men available for positions as teachers, as specialists, and as organizers in field demonstration work. It is, therefore, highly important that the agricultural college students who are not vet subject to the draft, as well as those who have been excused from military service, remain in college and make the best of every opportunity to prepare themselves for these heavier burdens, and it is incumbent upon the colleges of agriculture not only to urge this point of view, but to provide for these voung men the best teaching and the most thorough training to be had."

Something can doubtless be done in many colleges to provide special courses to meet the emergency needs. Thus, as regards the training of teachers, the same committee states that whereas at the outbreak of the war there were upwards of a thousand college-trained young men teaching agriculture in schools below college grade, the number has now been seriously depleted, while the development of work under the Federal Vocational Education Aid Act alone will create a demand for several hundred additional instructors with such training. It is suggested that the colleges can do much to "prevent the serious lowering of standards by increasing their facilities for training undergraduates for the teaching profession, by conducting emergency courses for teachers now in service, and by the intensive training along agricultural lines of college graduates in arts and science courses."

In some States the pressure upon students to return to the farms has been lessened and considerable assistance rendered in alleviating the labor problem by shortening the college year and providing a more intensive training. Many institutions deferred the opening of their doors until October, and others made special provisions for students whose return was retarded because of farm needs. The University of Nebraska has already announced its intention of closing its school of agriculture early in March next year and the college of agriculture early in April.

Recognition of the work of students leaving before graduation to engage in war service by some form of war certificate has been suggested by the executive committee of the Association of American Agricultural Colleges and Experiment Stations. It was pointed out that such a certificate would not only be much appreciated by many former students and their relatives, but would also serve to strengthen the bond between the student and the institution, and perhaps facilitate and render more probable his eventual return for the completion of his work.

Emergency short courses in agriculture have already been offered by a number of institutions and their further development seems logical. One interesting innovation along this line is being undertaken at the University of California, which is offering to a limited number of inexperienced men practical training as milkers, teamsters, and other branches of farm labor. Such courses, if successful, would help relieve the dearth of labor and it is possible that modifications of the idea might be worked out to attract greater numbers of town and city-bred boys to regular college work. One large college of agriculture in the Middle West reported that an increasing realization of the need for practical farm experience had in a measure decreased the registration from the cities in recent years, and the present inquiry indicated that the war had thus far not materially affected the proportion of country and city-bred students. It is well understood that the city-bred boy in the agricultural college has in the past been more or less of a problem, but his presence there in increasing numbers would at least possess the advantage of not diminishing appreciably the supply of available farm labor, while under the present conditions provision for the necessary farm experience before graduation would probably be found somewhat less difficult than formerly.

Serious as the shrinkage of students appears, it need not prove an absolute calamity. The efficiency of educational institutions is not measured by the enrollment, and this is specially true of the agricultural colleges, the tuition fees in which constitute under normal conditions little over 10 per cent of their income. To quote again from the committee on instruction in agriculture, "during the past fifteen or twenty years nearly every agricultural college in the country has been working at high pressure. Nearly all of them have been growing more rapidly in enrollment than in teaching staff and equipment. The result has been crowded class rooms, large laboratory sections, many hours in class and laboratory for teachers with correspondingly few hours for preparation, and too much of a tendency to get things done somehow, whether well done or not.

"Just now there seems to be a breathing spell so far as the resident teaching work is concerned. There are fewer students, probably 30 per cent less. The class rooms are less crowded. The sections are smaller, and the number of students each instructor is required to teach has in many cases decreased. The present time seems, therefore, to be opportune to consider how we have been doing things and how we may do better."

The committee was of the opinion that for these reasons not within a decade "has there been a time so favorable for giving serious attention to measures for improving the quality of teaching in the colleges themselves as the present war emergency affords." It is to be hoped that this optimistic view will prove justified, though there should not be overlooked the serious depletion of faculties or the possibility that in some States the reduction in enrollment may afford a pretext for a curtailment of financial support.

The decreased burden of teaching may also open up opportunities in many cases for greater attention to research and extension work. It may thus permit, for example, considerable additional investigation and experimentation which has a definite and direct bearing on present agricultural problems and so render a most timely and valuable service.

If the reduction in enrollment of agricultural students by nearly one-third seems discouraging, it is well to reflect that in England wholesale losses of faculties and students have occurred, that several institutions have closed their doors, and that others have been very seriously restricted in their operations. Likewise the Ontario Agricultural College reports a smaller registration in the entire institution than in its freshman class prior to the war. In our own country no such developments are expected and often the enrollment is far in excess of that of a few years ago. Some of this difference is probably due to the fact that in this country the principle of selective service was adopted as the basis of raising the National Army. When the importance of trained agricultural leadership becomes thoroughly realized, particularly in its relations to the existing emergency, there need be little doubt that the agricultural colleges, as the training ground for such leadership, will receive and retain the full support in every direction which they will need for this vital service.

# RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Chemical studies in making alfalfa silage, C. O. SWANSON and E. L. TAGUE (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 6, pp. 275-292).—This is a preliminary report of two series of experiments on chemical studies in the making of alfalfa silage, carried out at the Kansas Experiment Station. The first series of experiments, started in 1912 and continued for four years, was carried out in quart milk bottles; the second series, started in 1914 and continued in 1915, in 10-ton experimental silos. A portion of the work has been referred to (E. S. R., 37. p. 671), and a complete report will be published later. The conclusions drawn by the authors are based on the results obtained from both series of experiments.

It was found that silage could be made from alfalfa alone if absolute exclusion of air and retention of carbon dioxid could be secured. These conditions are, however, indicated as not practical of realization. The addition of supplements was found to insure a more rapid and plentiful production of acids, which makes conditions for putrefactive organisms unfavorable. Wilted alfalfa was more suitable for silage than unwilted. The addition of water to unwilted alfalfa was harmful, while no decisive results were obtained by the addition of water to wilted alfalfa.

Molasses was found to be the most effective supplement tried. Germinated corn was more effective as a supplement to alfalfa than sound corn, the results produced being similar to those produced by molasses. It is indicated that rye would be a suitable supplement but for the strong odor which it imparts to the silage.

The value of tightness of packing lies only in the fact that it makes the exclusion of air more certain.

In good alfalfa silage about one-third of the nitrogen was found to be in the amino form, while in bad silage the amount was sometimes one-half that of the total nitrogen.

"Most of the acids present in alfalfa silage are produced in the first two weeks. The percentage of acidity may increase after that, but the increase is comparatively slight. The alfalfa, as it is put into the silo, contains only a small amount of nitrogen in amino form. Most of the change of nitrogen into amino form takes place in the first 10 days. Silage from wilted alfalfa contains more nitrogen in this form than that made from fresh alfalfa. Sugar present in the materials used in making silage disappears very rapidly. Completely matured silage contains no sugar."

The isolation of parahydroxybenzoic acid from soil, E. H. WALTERS (Jour. Amer. Chem. Soc., 39 (1917), No. 8, pp. 1778-1784).—An aromatic acid whose identity with parahydroxybenzoic acid was established was isolated from a

sandy soil from Florida. Benzoic acid was also isolated from this soil, but in a much smaller quantity.

Parahydroxybenzoic acid was isolated by the extraction of 23 kg, of soil with about 75 liters of an aqueous 2 per cent solution of sodium hydroxid at room temperature for 24 hours. The extract was acidified slightly with sulphuric acid and filtered. The acid filtrate was extracted with ether, the ether extract concentrated to a volume of about 200 cc., and then treated with a concentrated solution of sodium bisulphite to remove aldehydes, etc. The bisulphite solution was drawn off and extracted several times with fresh ether, and the ether extracts combined and slowly evaporated on the surface of a small volume of warm water. The water solution was heated to boiling and filtered while hot to remove any insoluble oily residue. A crystalline compound separated from the cold concentrated aqueous solution. This was purified by re peated crystallizations from water, but the product thus obtained persistently retained a slight tinge of color which was removed only after many crystallizations and boiling with a small quantity of purified bone black. Much of the material was lost in this procedure. The aqueous solution was finally subjected to steam distillation to remove benzoic acid and other volatile substances which might be present. The solution in the distilling flask was evaporated to dryness and the residue extracted with chloroform to remove final traces of benzoic acid. The substance was finally recrystallized from water.

The confirmatory tests of the acids are described and the significance of their presence in the soil discussed.

Studies on the seed of Spartium junceum, M. Raffo (Ann. Chim. Appl. [Rome], 7 (1917), No. 5-8, pp. 157-164).—The seed examined was found to contain a lipolytic enzym having but slight action in an acid medium, but a marked action in the presence of sodium carbonate.

A yield of about 10 per cent of a green-colored oil with an aromatic odor was obtained from the seeds. The following constants were determined for the oil Specific gravity at 15° C., 0.9403; refractive index at 25°, 73.5; acid value, 9.1; saponification value, 198.6; iodin value, 134; Hehner value, 89.85; and Reichert-Meissl value, 0.44. The fatty acids obtained from the oil yielded the following constants: Specific gravity at 17°, 0.9208; melting point, 26.6–27°; solidifying point, 21.3°. The oil is classed with the group of semidrying oils.

Occurrence of raffinose in the seed of the jute plant (Corchorus capsularis), H. E. Annett (Biochem. Jour., 11 (1917), No. 1, pp. 1-6).—The author reports the isolation of raffinose from the seed of the jute plant. The seed examined contained about 2.25 per cent of the sugar. The crude raffinose was obtained by precipitating an alcoholic extract of the seed (after previous extraction with ether and petrol) with ether. The impure material so obtained was recrystallized from 80 per cent alcohol, rosettes of white needles depositing in several days.

The confirmation tests are described in detail.

The chemistry of wood.—III, Mannan content of the gymnosperms, A. W. Schobger (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 748-750, fig. 1: Jour. Forestry, 15 (1917), No. 2, pp. 197-202, fig. 1).—Continuing the study previously noted (E. S. R., 37, p. 502), the author examined 22 different species of gymnosperms and 6 of angiosperms for mannan and found it present in appreciable quantities in all of the conifers, but absent in the hardwoods. The sapwood was generally found to contain larger amounts of mannan than the heartwood. The content was found to decrease from the base upward but was uniform throughout the heartwood in a radial direction.

The industrial importance of mannan in the production of ethyl alcohol from sulphite liquor and by the hydrolysis of sawdust with catalyzers is pointed out.

The mannan was determined by precipitation of the mannose formed on hydrolysis as mannose hydrazone.

The effects of exposure on some fluid bitumens, C. S. Reeve and R. H. Lewis (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 743-746, fig. 1).

The importance of uniform culture media in the bacteriological examination of disinfectants, J. H. Wright (Jour. Bact., 2 (1917), No. 4, pp. 315-346, figs. 4).—The results of the study reported show that variations in culture media are the cause of the majority of the discrepancies obtained in the bacteriological examination of disinfectants. The hydrogen ion concentration of the culture medium was found to exert important influences on its composition and on its suitability for the growth of the typhoid organism. A marked relationship between the hydrogen ion concentration of the culture medium and the resistance of the test organism to the action of disinfectants was observed.

"The most satisfactory and uniform results have been obtained with a culture medium in which the  $P_{\rm H}$  value falls between 6 and 7. This condition is easily obtained with a medium containing 10 gm. of Witte's peptone, 3 gm. of Liebig's meat extract, and 5 gm. of salt, boiled 15 minutes, filtered, tubed, and sterilized, with no attempt to adjust the acidity."

The experimental data are submitted in tabular and graphical form.

A simple ultramicroscope, C. C. Kiplinger (Jour. Amer. Chem. Soc., 39 (1917), No. 8, p. 1616, fiys. 2).—A simple apparatus, which has yielded good results in practice, and its manipulation are described.

Sampling tubes for manure, alfalfa, or other organic materials, A. D. Shamel (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 7, pp. 225-228, figs. 4).—A device for sampling organic materials is described and illustrated.

"The apparatus . . . consists of a tube somewhat similar in arrangement and appearance to the King soil tube. Two different sizes of sampling tubes have been made, one for use in sampling car load or other large lots of manure, and the other for sampling bales of alfalfa, bean straw, cornstalks, or other similar materials. The manure sampling tube is about 6 ft. in length and about 2 in. in diameter. One end is made with a sharp sawtooth-like cutting edge so arranged as to cut down through the manure somewhat on the principle of the knives commonly used for cutting hay in the stack. At the other end of the tube an extra ring of metal is welded onto the tube in order to give it added support. A hole is cut through this ring and the tube so that a handle can be pushed through it for use in twisting the tube when the sample is being taken."

A sampling press, W. B. CLARK (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 788-790, figs. 4).—An apparatus for the sampling of roots, tubers, melons, and such fruits as are easily separated from the seeds and skins, which consists essentially of a plunger and a cylinder, the latter having a stout sieve bottom, and its manipulation are described.

The apparatus has also been found to be well adapted for obtaining raw cultures of finely divided substance which is sterile except for such inoculations as may already exist in the interior of the material. It is indicated that, while this work has not been fully developed as yet, very satisfactory results have been obtained with ordinary precautions.

A new filter flask, J. A. Shaw (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, p. 793, fig. 1).—An apparatus which is considered equal to the ordinary filter flasks and superior to the use of a bell jar for suction filtration and its manipu-

lation are described. The flask is pear-shaped, with a wide-mouthed stopcock at the bottom and a heavy glass tubing leading off to the suction pump from near the flask mouth, which is of a size suitable to take the filtering funnel.

Advantages claimed for the flask are better air seals than those obtained with the bell-jar type of filter, and easy removal of the filtrate and washing of the flask, thus practically eliminating the danger of contamination.

A simple improvised apparatus for hydrogen sulphid precipitation under pressure, A. V. Fuller (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 792, 793, fig. 1).—The apparatus described consists of an ordinary 500-cc. Kipp generator provided with a two-holed rubber stopper which carries a one-way stopcock and a small-bore glass tube about 3 ft. long which terminates at its upper end in a reservoir bulb of about 100 cc. capacity. The lower end of this tube extends several inches below the acid level. The gas outlet is fitted with a rubber stopper carrying a two-way stopcock. The manipulation of the apparatus is described.

It is noted that the precipitates obtained appear very granular and settle readily. The point of saturation is easily determined by rotating the flask and noting the absence of gas bubbles.

A method of ashing organic materials for the determination of potassium, P. L. Blumenthal, A. M. Peter, D. J. Healy, and E. J. Gott (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 753-756).—To reduce materially losses by spattering and volatilization in ashing organic material, the authors, at the Kentucky Experiment Station, have found that direct evaporation of the sample with nitric and sulphuric acids preliminary to burning off organic matter has proved the best method for securing uniform results. Simple moistening of the sample with sulphuric acid was found not to be sufficient, and enough acid must be added to oxidize the carbon and to convert all inorganic elements present to sulphates. This conversion of the potassium salt present in the material to the sulphate reduces the volatilization losses to a minimum.

Burning off the carbon in a muffle furnace yielded more uniform results than direct heating over a free flame.

The data are submitted in tabular form and discussed.

A practical revision of the cobalti-nitrite method for the determination of potash, R. C. Haff and E. H. Schwabtz (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 8, pp. 785, 786).—The following revision of the procedure previously described by Bowser (E. S. R., 22, p. 510) is submitted:

To a 2-gm. sample of raw material 0.5 gm. of ammonium chlorid is added and thoroughly mixed in a mortar. Four gm. calcium carbonate is then added and the contents of the mortar further mixed and ground. The mixture is transferred to a 20-cc. platinum crucible, the bottom of which has been covered with a generous layer of calcium carbonate, usually about 2 gm., the contents of the crucible are covered with about 2 gm. of calcium carbonate, and the heating and sintering carried out as in the J. Lawrence Smith method. After the mass has been slaked in a small casserole it is placed on a hot-water plate and heated to boiling, filtered into a flat-bottomed porcelain dish, and the precipitate washed three or four times with very hot water. An excess of acetic acid (5 to 10 cc.) is added to the filtrate and the solution then evaporated on a steam bath until no odor of acetic acid remains.

The residue is taken up with a little hot water and the sides of the dish thoroughly washed. From 10 to 15 cc. of the cobalt reagent is added and the liquid evaporated on a steam bath to a pasty consistency. It is removed from the bath, cooled, and about 30 cc. of cold water added, breaking up the precipitate thoroughly. The precipitate is then filtered through an asbestos padded Gooch crucible, washed once with cold water, the contents of the crucible trans-

ferred to a 400-cc. beaker containing an excess of standard fifth-normal potassium permanganate, and diluted to 250 cc. The beaker is then placed on a steam bath for about 15 minutes and acidulated with 10 cc. of 1:1 sulphuric acid, the excess permanganate is removed with standard fifth-normal oxalic acid, and the clear solution retitrated with standard potassium permanganate solution.

For determining "water-soluble" potash 10 gm. of the material is weighed into a 600-cc. beaker and boiled with 250 cc. of water for 30 minutes. It is then transferred to a 500-cc. flask, cooled to room temperature, and made to the mark. After shaking well, a portion of the solution is filtered through a dry paper and 50 cc. of the filtrate placed in a platinum or porcelain dish. The procedure is then carried out as given above.

Directions for preparing the cobalt-nitrite solution and calculation of the potassium oxid factor are given.

The method has been used for some time and has yielded most satisfactory results on total potash when checked against the J. Lawrence Smith method, and on water-soluble potash when checked against the official method.

The solubility of calcium phosphates in citric acid, A. A. RAMSAY (Jour. Agr. Sci. [England], 8 (1917), No. 3, pp. 277-298).—The results of the study reported show that the materials sold as "phosphate of lime" and "Calcii Phosphas B. P." are not tricalcium phosphate, but mixtures of di- and tricalcium phosphates. By adding disodium phosphate to ammoniacal calcium chlorid a mixture of di- and tricalcium phosphate and calcium hydrate is obtained. Bone ash dissolved in hydrochloric acid and precipitated with ammonia (as in the directions for preparing tricalcium phosphate according to the British Pharmacopæia) also yields a mixture of di- and tricalcium phosphate and calcium hydrate. When three equivalents of calcium oxid act on one equivalent of phosphoric acid and the resulting precipitate is immediately removed pure tricalcium phosphate is obtained. When two equivalents of calcium oxid react on one equivalent of phosphoric acid the product obtained is not dicalcium phosphate, but a mixture of di- and tricalcium phosphate.

Of the total phosphoric acid of pure tricalcium phosphate 91 per cent is soluble in 2 per cent citric acid solution in 30 minutes, as determined by the method adopted for the determination of "citrate-soluble" phosphoric acid. By addition of calcium carbonate to a pure tricalcium phosphate the "citrate solubility" of the phosphoric acid is reduced from 91 to 84 per cent. It is noted that the 2 per cent citric acid solution is rather a solvent for lime than for phosphoric acid.

"Since tricalcic phosphate and dicalcic phosphate are both soluble in the prescribed 2 per cent citric acid solution the statement that dicalcic phosphate can be differentiated from tricalcic phosphate by means of the selective action of this solvent is untenable. It follows that the manurial value of phosphates can not be determined by a 2 per cent citric acid solvent in the method prescribed, and it therefore is a matter for consideration whether or not the further use of this method should be continued."

See also previous notes of Hopkins (E. S. R., 37, p. 214) and Jatindra Nath Sen (E. S. R., 37, p. 615).

A method for the destruction of organic matter in animal and vegetable materials for the determination of arsenic and the examination of the ash, A GAUTIEB and P. CLAUSMANN (Compt. Rend. Acad. Sci. [Paris], 165 (1917), No. 1, pp. 11-16).—The procedure, which consists essentially of heating the dry, finely pulverized material with calcium oxid, is described in detail. The method can also be used for preparing material for the determination of boric, phosphoric, and silicic acids, fluorin, nickel, silver, and copper. The procedure rec-

ommended eliminates the use of large amounts of acid ordinarily used for oxidation.

Iodometric determination of chlorin in chlorids, G. Tobossian (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 751, 752, fig. 1).—In the proposed method the sample is mixed with finely powdered manganese dioxid and treated with sulphuric acid (1:1 by volume) in a distilling flask. The chlorin produced by the interaction of the  $\rm MnO_2$  and liberated hydrochloric acid is distilled into potassium iodid solution and the liberated iodin titrated as usual with tenthnormal sodium thiosulphate.

Comparative analytical data with the standard silver nitrate procedure indicate the accuracy of the proposed method.

A new test for chlorin in drinking water and its application for the estimation of the chlorin present, R. L. M. Wallis (*Indian Jour. Med. Research*, 4 (1917), No. 4, pp. 797-799).—A colorimetric procedure which depends on the production of a yellow color in a solution of benzidine or tolidin by chlorin is described as follows:

To 100 cc. of the sample to be tested in a Nessler tube 1 cc. of a 0.1 per cent solution of benzidine in 10 per cent hydrochloric acid is added. The solution first becomes blue, but on stirring the blue color rapidly changes to a bright yellow. The mixture is allowed to stand for exactly five minutes and then compared with standards prepared under similar conditions.

The production of the color is not affected by the salts present in drinking water or other chemical reagents added for purposes of sterilization. The delicacy of the test is indicated by its being able to detect 0.005 parts per million of chlorin in drinking water.

For effective chemical sterilization of water 1 part of chlorin in 500,000 parts of water is considered necessary.

The chemical examination of potable waters.—I. Determination of organic matter, I. M. Kolthoff (*Pharm. Weekbl.*, 54 (1917), No. 22, pp. 547-553).—The addition of 5 cc. of four-normal sulphuric acid and 25 cc. of the remaining potassium permanganate to 100 cc. of the water sample and the determination of the excess potassium permanganate iodometrically after 24 hours is considered to be the best procedure for the determination of organic matter in potable waters and to yield satisfactory results.

A new method for the determination of aldehyde sugars, J. Bougault (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 26, pp. 1008-1011).—A new method for the determination of aldehyde sugars which depends on the oxidation of the aldehyde to the corresponding monobasic acid with iodin in the presence of sodium carbonate is noted. The presence of ketonic sugars does not affect the result. In mixtures containing sucrose and other nonreducing sugars the accuracy of the procedure depends on the relative proportion of the sugars present. With increasing amounts of nonreducing sugars the necessary correction increases, and so slightly diminishes the accuracy of the results. The principal disadvantage of the method indicated is the interfering action of other organic substances that are likely to be present with the aldehyde sugars.

The details of the reaction and of the method are reserved for a future communication.

The acid content of fruits, W. D. BIGELOW and P. B. DUNBAR (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 762-767).—The following results obtained in an examination of the acids found in various fruits are reported: Apple, cherry, and plum, malic only; banana, peach, persimmon, probably malic only; cantaloup, malic none, probably all citric; cranberry, citric probably predominates, malic also present; currant, citric probably predominates, malic sometimes present; gooseberry, malic and citric; pear, malic only in some

varieties—citric probably predominates in others with small amounts of malic; pomegranate, probably all citric, no malic nor tartaric; quince and watermelon, malic, no citric; and raspberry (red), probably citric only—malic, if present, in traces only. Apricots, blackberries, and huckleberries were also examined, but no definite results on their acid content were obtained.

The danger of drawing general conclusions as to the acid content of fruits from analysis of a limited number of varieties, or even samples, is indicated as being emphasized by the varying results obtained with pears.

A table giving results and references thereto as to the acids in various fruits reported by previous investigators is included.

Sources and composition of some commercial invert sugar sirups with notes on sorghum sirups, S. Jordan and A. L. Chesley (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 756-758).—This is a general discussion of the topics of methods of analysis, moisture-holding properties, specifications, and sorghum sirup. Analytical data, including invert sugar, sucrose, and ash of a number of sirups collected from various sources, are submitted.

Relative value of different weights of tin coating on canned food containers (Washington, D. C.: Nat. Canners Assoc., 1917, pp. 51+666, figs. 9).— This is the report of an investigation by a technical committee representing the National Canners' Association, the American Sheet and Tin Plate Company, and the American Can Company. Products from various parts of the country typical of those usually canned in tin were used. In general, no great differences in the products were observed by using tins with varying weights of coating.

Data relative to the discoloration of cans and average tin content of various products are submitted in graphical form. Other experimental and analytical data of the investigation are reported in detail in 10 appendixes.

War food, AMY L. HANDY (Boston: Houghton Mifflin Co., 1917, pp. IX+76, figs. 2).—This small volume gives directions for drying fruits and vegetables; preserving meat; canning with and without sugar; preparing jellies; salting; pickling; and making cider, potato, and corn vinegar.

The evaporation of fruits and vegetables, J. S. Caldwell (Washington Sta. Bul. 148 (1917), pp. 7-111, figs. 26).—This is in part a revision of the bulletin previously noted (E. S. R., 35, p. 418), with new sections discussing in detail the drying of cherries, berries, peaches, apricots, prunes, and various vegetables, together with directions for preparing the materials for drying and for storing and packing the dry products.

A new method for the preparation of pectin, J. S. Caldwell (Washington Sta. Bul. 147 (1917), pp. 3-14).—A method of preparing pectin from cull apples or other fruits rich in the substance for future use in jelly making from fruit juices poor in pectin is described. The method consists essentially of the separation of a portion of the water of the juice by freezing, removal of the concentrated liquid from the ice by centrifugalization (or draining through muslin), and repetition of the process until the desired concentration has been obtained. The concentration is finally completed by evaporating the residue at a low temperature. The method has been simplified and adapted so that it may be easily carried out with very little equipment.

The concentrated extracts were found to retain their gelatination properties perfectly after long periods if the acid was removed from the juice by calcium carbonate. A tasteless and odorless dry product may be secured by precipitating the pectin from the concentrated extract by alcohol and subsequently drying at a low temperature.

Some general notes on the occurrence, distribution, and use of pectin are included.

Carbonation studies.—I, A mechanical stirrer for carbonation direct in the bottle, H. E. PATTEN and G. H. MAINS (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 787, 788, figs. 2).—An apparatus and its manipulation are described in detail.

Vinegar investigation.—A study of the changes that cider undergoes during fermentation and prolonged storage and its subsequent conversion into vinegar in rotating generators, B. G. Hartman and L. M. Tolman (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 759-762).—The results of the investigation, which extended over a period of two years, show that during fermentation a large part of the malic acid of the apple juice is destroyed to form factic acid. During acetification the remaining malic acid is almost entirely oxidized. The fixed acid in the vinegar is chiefly factic acid. The presence of acetates in the vinegar and indications of minute amounts of formic acid were demonstrated. Analysis of the ash showed it to contain 75 per cent of potassium carbonate.

Complete analytical data are submitted.

Preserving fish for domestic use, H. F. Moore (U. S. Dept. Com., Bur. Fisheries Econ. Circ. 28 (1917), folio).—This circular gives detailed general directions for canning and salting fish for home consumption.

A practical small smokehouse for fish (U. S. Dept. Com., Bur. Fisheries Econ. Circ. 27 (1917), pp. 7, figs. 3).—This gives directions for constructing the smokehouse and cleaning, salting, and smoking the fish, and discusses the fuel used in smoking and protection from mold.

## METEOROLOGY.

New methods of weather prediction, A. Voss (Mitt. Deut. Dendrol. Gesell., 24 (1915), pp. 133-149, figs. 2).—The author points out certain alleged deficiencies in ordinary methods of weather forecasting, particularly from the standpoint of the farmer and gardener, and explains methods devised by himself which he thinks overcome these deficiencies.

Factors influencing the condensation of aqueous vapor in the atmosphere, A. Masini (Nuovo Cimento, 6. ser., 12 (1916), II, No. 9, pp. 110-129, fig. 1; abs. in Sci. Abs., Sect. A.—Phys., 20 (1917), No. 235, pp. 261, 262; Sci. Amer. Sup., 84 (1917), No. 2180, p. 238).—Experiments bearing upon the action of ozone, nitrogen peroxid, and, indirectly, ammonia, as well as of dust, in forming condensation nuclei in the atmosphere are reviewed. The effect of electrical discharges, flames, and glowing bodies in favoring condensation is also referred to.

Ultraviolet light is not considered necessary for the formation of nuclei and functions only as a source of ozone. Gaseous ions exhibit no power to constitute condensation nuclei. "Trees, especially tall ones and those rich in resins, give rise to ozone, and should therefore favor production of rain. Opinions on the actual influence exerted by trees are, however, very variable."

The relation between forests and atmospheric and soil moisture in India, M. Hill [Indian] Forest Bul. 33 (1916), pp. 41, pls. 2; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 8 (1917), No. 4, pp. 554-556; Nature [London], 99 (1917), No. 2492, pp. 445, 446).—This is a report based upon replies to a letter of inquiry sent out by the Government of British India, asking information regarding (1) rainfall, (2) differences in level of the underground water table, and (3) flow of rivers and streams in different parts of India.

The data obtained indicate that during the last 50 years there have been no permanent changes in the rainfall which can be directly connected with the monsoons. It appears, however, that forests may increase rainfall to a certain

limited extent (not exceeding 5 per cent) by promoting the condensation of aqueous vapor. There appears to have been no change in the level of the underground water during the last 50 years, except such as depends upon the rainfall. Apparently in most Provinces there has been no serious damage to the flow of rivers and no great injury to cultivation as a result of floods due to forest denudation. There are, however, local exceptions, and much flood damage has been done in the Punjab, in Bengal, and in Assam.

Rainfall and gunfire, A. Angor (Compt. Rend. Acad. Agr. France, 3 (1917), No. 18, pp. 501-508; rev. in Nature [London], 99 (1917), No. 2493, pp. 467, 468; Sci. Amer. Sup., 84 (1917), No. 2180, p. 227).—This paper deals with the historical aspects of the subject, reviews the various theories advanced, and adduces evidence to show that there is no causal relation between gunfire and rainfall.

Correlation between atmospheric phenomena and the yield of crops (Rev. Sci. [Paris], 55 (1917), No. 14, p. 436).—This is a brief note on studies by Marenghi on the influence of precipitation on the yield of alfalfa, in which a record was kept during 10 years of the spring rainfall and of the yield of the crop. The coefficient of correlation was found to be 0.49 for the particular period and place in which the studies were made.

Phenological observations in the British Islands, J. E. CLARK and H. B. Adames (Quart. Jour. Roy. Mct. Soc. [London], 43 (1917), No. 183, pp. 285-316, figs. 2).—Observations from December, 1915, to November, 1916, at 117 stations on wild plants, birds, and insects are summarized. Tentative isophenal lines or zones similar to those of Ihne for Continental Europe are shown for several flowering plants for periods of 120 (April 29), 130 (May 9), and 140 days (May 19) for the British Isles. The usual data for farm crops are not included, although the status of farm work and crops at different dates is noted.

Climatological studies.—German East Africa, H. G. Lyons (Quart. Jour. Roy. Met. Soc. [London], 43 (1917), No. 182, pp. 175-195, pls. 8, figs. 5).—This article is based upon observations covering the 20 years from 1892 to 1911.

"On account of its position close to the equator most of the colony receives heavy tropical rains in the wet season, while the drier northeasterly and southeasterly air currents of northern and southern Africa, respectively, sweep over it and give rise to dry seasons which are in some parts of several months' duration and of considerable aridity." Seasons, as understood in the Temperate Zone, do not exist, but instead there is an alternation of the dry season and the rainy season which divides the year and determines the cycle of agricultural operations. The coastal region, as a result of air currents from the Indian Ocean, has a heavier rainfall than many parts of the interior.

Such climatic variations as occur are largely those due to the physical character of the country. The climatic conditions of each district are discussed in some detail with reference to vegetation.

# SOILS—FERTILIZERS.

The soil solution obtained by the oil pressure method, J. F. Morgan (Soil Sci., 3 (1917), No. 6, pp. 531-545).—Experiments at the Michigan Experiment Station with the paraffin oil displacement-pressure method are reported. In this method the solution is displaced by forcing paraffin oil by pressure through the soil.

It was found that "the paraffin oil pressure method furnishes in most cases plenty of solution for the necessary analytical work. In sandy soils as high as 74 per cent of the moisture present in the soils was obtained. A large amount

of solution may be obtained without its coming in contact with the oil. If it does it can be easily separated by cooling and by the separatory funnel.

"The concentration of the soil solution from different samples of the same type of soil varies according to the moisture content of the samples from which it is derived. Successive portions of the same extraction vary only slightly in their physical properties, but to a considerable extent in the various forms of nitrogen. The forms of nitrogen vary in the different solutions. . . . Calcium and magnesium also vary according to the treatment and reaction of the soil. The phosphoric acid is fairly constant. Potash varies somewhat. A small percentage of the bacteria are removed from the soil, since the soil acts as a filter. Anaerobic changes take place in the cylinder if it is allowed to stand for a long time.

"The paraffin oil displacement-pressure method furnishes . . . a fair representative of the solution as it exists in the soil. The method permits the use of a large amount of soil, thus a better representative sample. Work now in progress indicates that it furnishes a valuable index of the microbial changes in the soil."

Is the humus content of the soil a guide to fertility? R. H. Caer (Soil Sci., 3 (1917), No. 6, pp. 515-524, figs. 3).—Experiments conducted at Purdue University using a surface clay soil very deficient in organic matter and different organic manures are reported.

"The results of the vegetation and humification tests seem to show that whenever there is rapid humification of manure the growth of the plant is greatly stimulated, indicating that 'the decay of organic matter is desirable in plant growth and not just its mere presence.' This was especially noticeable when green manures were rolled under and limed as compared with disking or mixing the manures uniformly with the soil.

"Certain of the manures seem to be as soluble in a 4 per cent ammonia when just mixed with the soil as after humification. This was found to be true with alfalfa and steer and somewhat with cow manures. Horse manure seemed to humify slowly and its plant food was largely unavailable to corn during the first year, but the humification and vegetation tests show it becomes more available in the second year. It was possible to increase the rate of humification of horse manure in the first year by adding dolomitic limestone, which resulted in a greater yield of corn than where humification had not taken place.

"The organic residues left in the soil from manure treatment were not very effective during the second year in producing a growth of corn, probably because the most available or valuable complexes had disappeared in the first year. There is no apparent relationship between the percentage of ash in humus and the growth of corn. The humification and vegetation tests seem to indicate a rather close relationship between the amount of humus and the growth of corn."

Effect of the addition of organic matter to the soil upon the development of soil acidity, M. F. Miller (Missouri Sta. Bul. 147 (1917), pp. 50, 51).—The results reported in general indicate "that the ordinary green manures turned under either dry or fresh do not increase soil acidity, although a crop containing much sugar, as in the case of sorghum, does appreciably increase soil acidity for a few weeks. This acidity later decreases."

Is there any fungus flora of the soil? S. A. Waksman (Soil Sci., 3 (1917), No. 6, pp. 565-589).—Studies at the New Jersey Experiment Stations of the fungus content of 25 soils collected under sterile conditions from different parts of North America and the Hawaiian Islands are reported.

Over 200 species of fungi were isolated. It was found that the more fertile soils contained more fungi, both in number and species, than the less fertile

soils. The soils of the cooler climate seemed to contain a greater number of Mucorales and Penicillium, while those of the warmer climate were more abundant in Aspergillus. The acid and water-logged soils were richer in numbers and species of Trichoderma than normal agricultural soils.

Biological variations in soil plats as shown by different methods of sampling, F. E. Allison and D. A. Coleman (Soil Sci., 3 (1917), No. 6, pp. 499-505, figs. 2).—Experiments conducted at Rutgers College to determine the influence of method of sampling soils on biological variations are reported. Two one-twentieth acre plats, one of heavy clay growing timothy sod and the other of sandy loam growing corn, were used. Samples were taken by the Brown method (E. S. R., 28, p. 120) and by the Lipman sampling tube (E. S. R., 14, p. 556).

The data obtained led to the belief that "where plats are uniform in character the biological variations of the soil at different points in the plat are not great, or else we are not able to detect these differences by the present methods. The tube method is superior to Brown's method both for ease of taking the sample and from the standpoint of destruction of the plat, especially in an uncultivated area."

The effect of sterilization of soils by heat and antiseptics upon the concentration of the soil solution, G. P. Koch (Soil Sci., 3 (1917), No. 6, pp. 525-530).—Experiments conducted at Rutgers College to determine the influence on the concentration of the soil solution of commercial sterilization as practiced in greenhouses, sterilization as used in biological laboratories, and of the presence of organic matter during the process of sterilization are reported. The following conclusions were drawn:

"The lowering of the freezing-point method is a satisfactory means of determining soil solution concentration as influenced by sterilization. In commercial as well as laboratory methods of steaming soils, the heavier soils are more influenced by sterilization than lighter soils. Steaming alone was more effective in increasing the concentration than . . . the formalin treatments.

"Applying formalin (1:50) and then steaming at 10 lbs. pressure increased the concentration more than any other method tried. By this method the concentration was increased to three times the original concentration of the soil solution. A considerable amount of soluble material is leached out of the soil, and thus the concentration is lowered if the quantity of antiseptic solution applied is so great that the soil can not hold it against the force of gravity. . . .

"Sassafras loam and . . . Penn loam soils were affected in the laboratory sterilization method so that the concentration was increased 0.24 and 0.3 atmosphere, respectively. The concentration of . . . Norfolk sand containing a very small amount of organic matter was not affected so that it could be detected by the method employed. One per cent of dried blood increased the concentration of the soil solution of . . . Norfolk sand 0.09 atmosphere, while 2 per cent cotton-seed meal increased the concentration three times this amount."

Some effects of organic growth-promoting substances (auximones) on the growth of Lemna minor in mineral culture solutions, W. B. BOTTOMLEY (Proc. Roy. Soc. [London], Ser. B, 89 (1917), No. B 621, pp. 481-507, pls. 2, figs. 7).—Experiments on the influence of extracts of bacterized peat on the growth of L. minor plants in mineral culture solutions showed that "the addition to the mineral culture solution of 368 parts per million of organic matter from the water extract of bacterized peat resulted, after six weeks, in a multiplication of the number to 20 times, and an increase in weight to 62 times, that of the control plants. The water extract free from humic acid, representing an addition of 97 parts of organic matter per million, gave  $9\frac{1}{2}$  times the number and 29 times the weight; 32 parts per million from the alcoholic extract

gave 3½ times the number and 7½ times the weight; 13 parts per million from the phosphotungstic fraction gave 1½ times the number and 2½ times the weight.

"The effect of the reduction in amount of auximones with successive fractionation of the bacterized peat was also manifest from the general appearance of the plants. Those in mineral nutrients only decreased in size week by week, and became very unhealthy in appearance, while there was a progressive improvement in the appearance of the plants supplied with increasing amounts of auximones. Those receiving the larger amounts retained their normal healthy appearance throughout the experiment and increased in size.

"The beneficial effect of the auximones was not due to a neutralization of the toxic substances present in the ordinary distilled water, since comparable results were obtained with conductivity water. An interchange of culture solutions, with and without auximones, showed that the plants are very sensitive to the presence or absence of these substances. It is suggested that some of these growth-promoting substances may act directly as organic nutrients, and others may be of the nature of accessory food substances."

Du Page County soils, C. G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE, and F. W. GARRETT (Illinois Sta. Soil Rpt. 16 (1917), pp. 56, pl. 1, figs. 8).—Du Page County is located in northeastern Illinois within the late Wisconsin glaciation. The topography varies from rolling to slightly undulating. The natural drainage is said to be poorly developed.

The soils of the county are divided into upland prairie soils, rich in organic matter, upland timber soils, terrace soils, late swamp and bottom-land soils, and miscellaneous types. Of these the brown silt loam upland prairie soil covers 59.95 per cent, the yellow-gray silt loam upland timber soil, 20.65 per cent, and the black mixed loam bottom-land soil, 12.01 per cent of the area.

It is pointed out that the soils of the county vary widely in content of fertility constituents. "The deep peat contains in the plowed soil of an acre 18 times as much nitrogen as yellow silt loam, and about 5 times as much nitrogen, but only one-eighth as much potassium as brown silt loam. The total supply of phosphorus in the surface soil varies from 760 lbs, per acre in the yellow silt loam to 2,360 lbs, in the black clay loam. The amounts of magnesium and calcium vary from about 4,000 to 5,000 lbs, in some types to more than 20,000 lbs, in others. Some types contain an abundance of limestone; others are practically neutral or slightly acid; and still others, such as the yellow-gray silt loam and the brown sandy loam, are acid in the surface and more strongly acid in the subsurface, but sometimes contain an abundance of limestone in the subsoil. More than 90 per cent of the soils of the county contain no limestone in the surface or subsurface to a depth of 20 in."

Soil survey of Dickey County, N. Dak., T. M. BUSHNELL, E. H. SMIES, W. I. WATKINS, A. C. ANDERSON, M. THOMAS, M. E. STEBBINS, R. C. DONEGHUE, and J. W. INCE (North Dakota Sta. Bul. 121 (1917), pp. 5-56, pls. 2, fig. 1, map 1).—This survey has been previously noted (E. S. R., 36, p. 421).

Sand devastation, P. Collins (Sci. Amer. Sup., 83 (1917), No. 2157, pp. 280-282, figs. 12).—Information on how sand dunes advance and how their movement is checked is given.

The improvement of the poor soils and run-down soils of New Jersey, J. B. R. DICKEY (N. J. Agr. Col. Ext. Bul., 1 (1917), No. 11, pp. 31, figs. 2).—This is a brief general statement of methods of improving and maintaining soil fertility, with special reference to the poor and run-down soils of New Jersey.

Manure and artificial fertilizers for peat soil poor in nitrogen, H. von Femilizen (Svenska Mosskulturför, Tidskr., 30 (1916), No. 5-6, pp. 409-436, tigs. 7).—Eleven years' experiments with manure and artificial fertilizers on

Swedish pear soil deficient in nitrogen showed that manure alone did not give good results but that excellent results were obtained with artificial fertilizers. It is concluded that manure should be used on such soils only in moderate amounts to stimulate bacterial action, while plant nutrients should be supplied by the use of artificial fertilizers. Manure also gave poor results on white moss soil previously treated with phosphates and potash.

American sources of nitrogen, T. H. Noston (Sci. Amer., 116 (1917), No. 16, pp. 394, 410, 411, figs. 4).—This is a review of the present situation with reference to the economic production in the United States of combined nitrogen for military, agricultural, and industrial needs.

The production of sulphate of ammonia for 1915–16 (New York: The Barrett Co., pp. 16, pl. 1, fig. 1).—This pamphlet summarizes data on the production of ammonium sulphate in the world during 1916, but states that no figures have been available from Germany since 1913. The production in the United States for 1916 is estimated at \$25,000 tons, an increase of 30 per cent over the figures for 1915. Of this production 272,000 tons are credited to coke ovens and 53,000 tons to gas works and bone carbonizing plants. The consumption of all forms of ammonia in the United States totaled \$15,424 tons in 1915 and \$47,706 tons in 1916.

Adsorption of ammonium sulphate by soils and quartz sand.—Preliminary communication, M. I. Wolkoff (Soil Sci. 3 (1917), No. 6, pp. 561-564).—A summary of the results of experiments at Rutgers College is reported on the adsorption of ammonium sulphate solutions of 1 2, 1 4, 1 8, 1 16, 1 32, 1 64, 1 128, and 1 236 normal concentrations by medium sandy loam, medium learn, medium silt loam, heavy silt loam, shaley loam, muck, and quartz sand passing the 24, 60, and 124 mesh and 5 0 and 7 0 belting cloth.

The results in general showed that with the increase in concentration of the ammonium sulphate solution the percentage of adsorption decreased, while the total amount of salt that went out of solution increased. The quartz sand did not wholly follow the general rule, as did the agricultural soils, for instead of the decrease of the concentration of the salt solution on its addition to the soil, its concentration became greater. This phenomenon was most pronounced in the coarse quartz sand and diminished with the increase in the fineness of the material. Also the effect was more noticeable in the more concentrated solutions than in those less concentrated. In the finer grades of the quarti treated with the comparatively dilute solutions the point was reached after which the concentration of the resultant solution in the mixture with sand was less than that of the original solution. After a certain point, which evidently is specific for a given quartz sand, the quartz sand followed the same general rule that soils follow. In the case of the coarse sand which is designated as 24 mesh the depression of the salt solution after application was greater in every instance than the depression of the freezing point of the solution before application. The percentage of the increase in depression, however, gradually decreased with the dilution of the applied solution. With the finer grade of the quartz sand (60-mesh) in the first three concentrations there was a striking similarity to the results obtained with the coursest material. But beginning with the concentration 1 32-normal, there was an adsorption of the salt by the quarts sand. the percentage of this adsorption increasing with the dilution of the solution.

"The results tend to show that the heavier the soil the greater is the amount of the salt adsorbed. The time in which the soil is allowed to be acted upon by the salt solution influences the percentage of the salt adsorbed. In the light sandy soil the maximum adsorption was reached in about 24 hours, while in the heavier type this point occurs after as many as 72 hours. The temperature from 0 to 31° C, at which the reaction is allowed to proceed affects the degree

of adsorption, this being greater at the higher temperature in a given time than at the lower one. The presence of the organic matter in the form of dried blood, cottonseed meal, alfalfa, barley straw, or wheat straw affects the adsorption of ammonium sulphate in the soil. Moreover, the application of these materials alone increases the concentration of the soil solution."

Saltpeter: Its origin and extraction in India, C. M. HUTCHINSON (Agr. Research Inst. Pusa Bul. 68 (1916), pp. 24, pls. 4).—The methods in use by the natives of India for the extraction of nitrate salts from soils and organic matter are described. It is pointed out that the present sources of saltpeter are not fully utilized on account of the native methods used and the low price of saltpeter. The native methods do not allow of recovery of all the nitrate present in the soil used. It is thought probable that owing to the favorable soil and climatic conditions in Bihar, artificial niter beds would form a useful additional source of nitrate.

Potash from incinerator ash of the Northwest, C. W. Thing (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 472-474).—Experiments conducted at the University of Washington on the extraction of potash from the ash of the burned waste from the lumber industry are reported. The following conclusions are drawn:

"Potash production from incinerator ash can not be put on a paying commercial basis . . . because of (1) low potash content, (2) higher cost of production, (3) insufficient supply of raw material. Unless a new method for the disposal of waste is suggested, the prevailing method of disposal of incinerator ash is as economical as can be found. Analyses show it to be of little value for fertilizer. If any plan were to be suggested for the successful production of potash from wood ashes, it must fulfill the following conditions: (1) Dispose of the waste as fast as it is produced; (2) operate at low temperatures and with slight draughts; (3) successfully meet foreign and domestic competition."

Tetraphosphate, G. Vinassa (Staz. Sper. Agr. Ital., 49 (1916), No. 7-8, pp. 357-365; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 10, pp. 1419, 1420).—A new phosphatic fertilizer called tetraphosphate is described, which has been recently put on the market as a substitute for basic slag. It is prepared by mixing powdered phosphorite with carbonates of the alkaline earths, at the rate of 6 per cent by weight of the carbonates, and heating the mixture to 400° C. in special ovens. The mass is then moistened and inert bodies are added until a substance containing 20 per cent total phosphoric acid is obtained. The finished product is a dry grayish-white powder almost insoluble in water, with which it gives an alkaline reaction, and partly soluble in acids which cause an evolution of carbon dioxid.

Tetraphosphate was treated with a number of solutions, including water; water saturated with carbon dioxid; sodium chlorid and nitrate; ammonium chlorid and sulphate; 18 per cent ammonium acetate; 40 per cent ammonium malate; 20 per cent ammonium tartrate; 40 per cent ammonium citrate; 0.5, 2, and 10 per cent citric acid; and a mixture of 4 per cent citric acid, 6 per cent formic acid, and 10 per cent sodium chlorid. Similar tests were conducted with Sfax phosphorite. The solution of citric and formic acids and sodium chlorid was proposed as a suitable reagent for tetraphosphate, but indicated a larger percentage of soluble phosphoric acid in phosphorite than in tetraphosphate. The same result was obtained with all the other solvent solutions.

"These results would indicate that no valuable changes take place when the phosphorite is heated with the carbonates of the alkaline earths, and that the process, which is complicated and costly, is also useless. The name tetraphosphate is very inappropriate, as its insolubility clearly proves it to contain neither tetraphosphate nor calcium silicophosphate, both of which products have been isolated from basic slag. From the purely chemical point of view, there is no analogy between basic slag and tetraphosphate, which may be simply considered a ground phosphate mixed with inert compounds."

Basic slag as affecting agricultural development, D. A. GILCHRIST and H. Louis (Jour. Soc. Chem. Indus., 36 (1917), No. 5, pp. 261-264).—This is a review of experience in Europe and the United States on the use of basic slag and rock phosphate for fertilizer, special attention being given to the difference between the citrate solubilities of the basic slag derived from the Bessemer steel process and of that derived from the English basic open hearth process.

The conclusion is drawn that "citric solubility is certainly not the only criterion, and is apparently not even a reliable criterion, of the value of phosphatic material as a manurial agent. It is therefore submitted that total phosphoric acid content is a far more reliable test of manurial value, and possesses the further advantage that it depends on the definite analytical determination of a substance, instead of being an empirical test liable to be affected by the conditions and methods of its application, and that it should therefore be authoritatively substituted for the citric solubility test throughout the country. This change would not only render available for the use of British agriculturists an annual amount which may reach up to 100,000 tons of phosphoric acid, most of which is now merely a troublesome waste product, but would at the same time render valuable assistance to the steel trade of the country."

The liming of limy lands, A. H. Rosenfeld (Internat. Sugar Jour., 19 (1917), No. 221, pp. 209-213).—Experiments conducted at the Tucumán Experiment Station in Argentina with lime on typical sugar cane soils which were high in lime, but low in carbon dioxid are reported. Unslaked lime was applied at the rate of 1,600 kg. per hectare (1,424 lbs. per acre). It was found that the cane crops on the limed plats were 5 tons per acre greater than on the unlimed, the cane sprouted better, and the average weight of the stalks for five years was almost 10 per cent better.

Rules and regulations for the enforcement of the lime-barrel act, S. W. Stratton (U. S. Dept. Com., Bur. Standards Circ. 64 (1917), pp. 6).—The text of these regulations, which should be of interest to users of agricultural lime, is given.

The fertilizer value of city wastes.—II, Garbage tankage.—Its composition, the availability of its nitrogen, and its use as a fertilizer, P. J. Schrokder (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 513-518).—In a second contribution to the subject (E. S. R., 36, p. 728) studies on the composition of garbage tankage, the availability of its nitrogen, and its fertilizer value are reported.

The examination of various garbage tankages "revealed no important fact that shows that they are unsuited for fertilizer material. The position is not taken that it is possible to determine the value of a fertilizer material definitely by present methods of chemical analysis, but from the examination the expectation would seem entirely justified that the proper use of garbage tankage should give the usual results obtainable from medium or low-grade fertilizers."

Turf bedding and compost, I. I. VIKHLIAEV (Torfiana Podstika i Kompost. Petrograd: Glav. Uprav. Zeml. i Zeml., Otd. Zemel. Uluch., Torfmeistersk. Chast., 1915, pp. 50, pls. 2, figs. 19).—A review is given of experience with turf and moss as a bedding for cattle and horses and as a manure.

The best material was young, not greatly decomposed, mossy turf. Sphagnum was also good for this purpose. Air-dried moss, frozen while damp, made

excellent bedding with very little dust. It was found to be very absorbent both of water and gases, destroyed disagreeable stable odors, and made an excellent small-grained manure which was easily and uniformly spread under the plow. Compressed turf was also found to be cheaper, occupy less storage space, and to be less dangerous as regards fire than straw. The resulting manure was found to contain from 0.5 to 1 per cent of nitrogen, 0.2 per cent of phosphoric acid, 1.3 per cent of sulphuric acid, 0.2 per cent of potassium, 1.2 per cent of calcium, and 2.1 per cent of magnesium.

Artificial fertilizers, their present use and future prospects, E. J. Russell (Jour. Soc. Chem. Indus., 36 (1917), No. 5, pp. 250-261, Ag. 1).—The author reviews the commercial fertilizer situation, dealing especially with the general production and use, manner of use, and results obtained therefrom in Europe under war-time conditions.

The American fertilizer handbook (Philadelphia: Ware Bros. Co., 1917, 10. ed., pp. [434], figs. 10).—This handbook contains the usual data and information relating to the fertilizer industry (E. S. R., 36, p. 124). Among the more important special articles included are the following: Dictionary of Fertilizer Materials, by T. C. Pinkerton; The Sulphuric Acid Industry, by A. M. Fairlie; Sulphate of Ammonia Statistics; Fertilizers and Farm Efficiency, by J. W. Henceroth; Use Fertilizers to Keep More Stock, by S. B. Haskell; Sulphur, by P. S. Smith; Potash Salts; 1915, by W. C. Phalen; and Potash, 1916, by H. S. Gale.

Commercial fertilizers, W. J. Jones, Jr., E. G. Proulx, R. B. Deemer, R. O. Bitler, and H. C. Mugg (*Indiana Sta. Bul. 199 (1917)*, pp. 3-114, figs. 2).—This is the report of official fertilizer inspection and analyses in Indiana for 1916. Including information on the selection, purchase, use, and home mixing of fertilizers.

Results of fertilizer inspection, spring season 1917, A. J. PATTEN (Michigan Sta. Circ. 35 (1917), pp. 3).—This is the report of fertilizer inspection and analyses in Michigan for the spring season of 1917. "Of the 518 samples analyzed, 135 (26 per cent) were found to be below guaranty in one or more constituents and 92 (17.8 per cent) were below guaranty in potash."

## AGRICULTURAL BOTANY.

Matroclinic inheritance in mutation crosses of Enothera reynoldsii, C. D. LA RUE and H. H. BARTLETT (Amer. Jour. Bot., 4 (1917), No. 3, pp. 119-144, figs. 4).—This paper is concerned primarily with the type of inheritance previously discussed (E. S. R., 35, p. 128) as mass mutation.

It has been found that the mutations characteristic of mass mutation in *E. reynoldsii*, when crossed either way among themselves or with the parent form, give progeny conforming exactly to the type of the pistillate parent. The author states that in *E. reynoldsii* mass mutation consists in the production of inordinate numbers of mutations of several characteristic types by certain individuals, which may be looked upon as having undergone a premutative modification. Their production of a large number of abortive seeds is regarded as one manifestation of mutability. The characteristic mutations form a series, each member of which may give rise to a succeeding member, such a series being that formed by the mutants semialta, debilis, and bilonga.

The observed facts of inheritance are supposed to be best explained by the hypothesis that two types of nonequivalent gametes, designated as  $\alpha$  and  $\beta$ , are normally produced, the  $\alpha$  gametes being usually eggs and the  $\beta$  gametes sperms, the mutant bilonga, however, producing both  $\alpha$  and  $\beta$  sperms. Mutatation in  $\alpha$  reynoldsii consists in the modification in  $\alpha$  gametes of factors

that have no counterpart in the  $\beta$  gametes. Sperms of the form *typica* being  $\beta$  gametes, mutations appear whenever a mutated  $\alpha$  gamete is fertilized. They do not appear as a result of segregation.

A new type of non-Mendelian variation in plants, S. IKENO (Bot. Mag. [Tokyo], 29 (1915), No. 346, pp. 216-221, fig. 1; abs. in Ann. Bot. [Rome], 14 (1916), No. 2, p. 109).—The author reports having found in heredity tests with Capsicum annuum that variegation was transmitted from either parent or both. The numbers produced, however, were smaller when variegated plants were crossed with green than with variegated ones, the Mendelian formula not applying in these results.

The relation between evaporation and plant succession in a given area, F. C. GATES (Amer. Jour. Bot., 4 (1917), No. 3, pp. 161-178, figs. 9).—Experimentation was carried on during the summers of 1915 and 1916 with 42 standard atmometers, employing the usual methods. Owing to the smallness of the area covered the influence of edaphic factors was not obscured by the operation of broad climatic factors.

Invasion, the initial stage of succession, must take place, it is claimed, under the conditions already existing. A change of conditions coincident with mesophytic succession may result in a decrease in the rate of evaporation in the ground or chamæphytic layer. Evaporation differences are due to the size and density of the surrounding vegetation. While a decrease in the evaporation is not a prerequisite to succession, a change in the dominant species of an area is fundamental thereto. The change in evaporation is a result and not a cause of succession. While certain species develop under existing conditions to bring about succession, species of narrower physiological limitations can not develop until the conditions come within their range. These are secondary species, unable to cause succession, the occurrence of which requires the arrival and development of the dominant species of a higher genetic association.

Adaptations of vegetation to climate, J. Massaet (Ann. Géogr., 26 (1917), No. 140, pp. 94-105, pl. 1).—This is an account of the conditions and behavior observed in a study of vegetation in portions of France which are subject to somewhat exceptional climatic and seasonal influences and changes. It is stated that each function in the economy of the plant, as germination, growth, rosette production, etc., has its optimum temperatures lying within limits which are more or less narrow according to species, and that in order to understand the adaptation of a plant to heat (as an example of influential climatic elements) it is necessary to study the plant in all the successive phases of its life and in relation to the various exigencies to which it is normally subjected.

Temperature and life duration of seeds, J. F. Groves (Bot. Gaz., 63 (1917), No. 3, pp. 169-189, figs. 5).—Employing Turkey red wheat, the author has sought to determine to what extent a study of the life duration of seeds at high temperatures (50 to 100° C.) will explain the process of degeneration of air-dried seeds at ordinary storage temperatures. The life durations of wheat with 9, 12, and 17.5 per cent moisture are given for various temperatures, and the degree of application at high temperatures of the Lepeschkin formula (E. S. R., 29, p. 27) is indicated.

No definite trend appears in the value of the temperature coefficient  $Q_{10}$  (symbolizing the Van't Hoff law), and its range is confined to rather narrow limits. It is held that there is no justification for placing much emphasis on predicted longevities at low temperatures.

This work indicates some of the possibilities of throwing light on the nature of the processes of the loss of viability in seeds in storage conditions, and it makes possible a quantitative statement of the significance of storage condi-

tions, especially moisture content and temperature as regards the longevity of seeds.

Duration of leaves in evergreens, VINNIE A. PEASE (Amer. Jour. Bot., 4 (1917), No. 3, pp. 145-160, flgs. 13).—Observations by the author in the western part of the State of Washington show that leaf persistence varies among evergreens from about 2 to 23 years. It is influenced by age and habitat, being shortened in saplings, by sunshine, on windward coasts, and in moist climates. Peat bogs show an influence similar to that of dry climate in the retention of leaves. Increased duration of leaves corresponds to such factors as favor slowness of growth, also decrease of leaf surface and of photosynthetic and transpiring activity. It is considered as possible that variations in leaf duration in a given species may be due to differences in transpiration or photosynthetic activity caused by a difference in age or habitat.

The reaction of plant protoplasm, A. R. Haas (Bot. Gaz., 63 (1917), No. 3, pp. 232-235).—Determinations of the actual and total acidity of a number of plant tissues are said to have shown that there is no constant relation between the two. Great variations occur in different portions of the same plant, one case (that of cranberry fruits) showing an actual acidity of 4/1,000 normal in the living cells.

The mode of action of plant peroxidases, G. B. REED (Bot. Gaz., 62 (1916), No. 3, pp. 233-238, figs. 2).—Having followed up the work previously noted (E. S. R., 35, p. 713), the author reports on a study of the very active ferment of horse-radish obtained after soaking the finely chopped tissue in water for 24 hours.

The results, as detailed and shown in graphical form, are considered to indicate that just as colloidal platinum is recharged with oxygen by hydrogen peroxid as soon as some of the oxygen has been removed by a reducing agent, so the horse-radish peroxidase is recharged by hydrogen peroxid under similar conditions. A study of potato peroxidase gave similar results. It is thought that in such oxidation processes the peroxidase combines with oxygen to form an intermediate compound which is a more energetic oxidizing agent than the original source of the oxygen, the final stage in the oxidation being thus affected by this intermediate compound. It is thought that this throws an important light on the difficult question of the mechanism of oxidation in living tissues.

The supposed action of potassium permanganate with plant peroxidases, H. H. Bunzel and H. Hasselbring (Bot. Gaz., 63 (1917), No. 3, pp. 225-228).—The authors describe experimentation and other data which are considered to indicate that the conclusions drawn by Reed, as above noted, are too sweeping for the experimental grounds upon which they are based. The oxidation phenomena observed by that author are thought to have been brought about by the action of manganese peroxid and not by activated plant peroxidases.

The response of plants to illuminating gas, Sarah L. Doubt (Bot. Gaz., 65 (1917), No. 3, pp. 209-224, figs. 6).—The author, studying the effects of illuminating gas on flowers, potted plants, and root systems of a number of plants, found that certain ones named were injuriously affected by proportions of gas far below the limits of perceptible odor. An ethylene content corresponding to that of ordinary illuminating gas gave unfavorable results with several species. Some were not materially injured unless the odor was noticeable, and two were very resistant to gas. Lists are given of plants injured by gases in the soil, with forms of injury suffered by them.

Young trees at least may be injured by leakage of gas imperceptible to the senses, the foliage showing no indication of injury above ground. The killing of trees by gas is thought to be a slow process, sometimes requiring months or

years. It appears that a perceptible odor of gas near trees is a certain indication that they are being injured.

Damage resulting to greenhouse crops and soil from escaping illuminating gas, G. E. Stone (Florists' Ex. 42 (1916), No. 2, pp. 61, 85, fig. 1).—Cases are cited in which illuminating gas was known to travel for considerable distances under frozen soil or more or less impervious strata, or to escape otherwise and injure vegetation in ways which are described, even when the concentrations were hardly, if at all, noticeable to the sense of smell. Roses are extremely sensitive to gas poisoning, and Easter lilies are greatly stunted thereby. Gas in the soil may be taken up by water and carried to plants some distance away. Sewer gas may be injurious if abundant, and certain paints give off gases which are injurious. On the other hand, certain gases in low concentrations are stimulating to growth.

A plan is presented for the protection of plants near a leaking pipe, consisting of a covering like an inverted trough for the gas main and connecting pipes to carry the gases to the open air, where they do comparatively little damage.

Leaf nectaries of Gossypium, E. L. Reed (Bot. Gaz., 63 (1917), No. 3, pp. 229-231, pls. 2, fig. 1).—The author describes certain nectar glands found on the midrib and other principal veins of leaves of G. hirsutum.

On the formation of nodules in the cortex of Hevea brasiliensis, G. BRYCE (Dept. Agr. Ceylon Bul. 28 (1916), pp. 23).—Giving a somewhat detailed account of nodular and related structures in H. brasiliensis, the author states that such nodules are produced as the result of an alteration in the content of the latex vessels. This has not been referred to any parasitic organism and is thought to be due to physiological changes in the latex, certain trees showing a predisposition to develop this condition on tapping. Four types of nodule are described.

Globular shoots are to be distinguished from nodules, being formed by the growth of latent buds and never forming a core or the large masses of woody tissue sometimes resulting from nodule growth.

Nodules formed around altered latex vessels do not appear on trees that have not been tapped. These structures are formed on Hevea both in its native habitat and in plantations. The condition is not infectious.

Preliminary observations on the distribution of certain hymenomycetes and on their probable relation to the ectotrophic mycorrhiza of phanerogams, B. Peyronel (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 26 (1917), I, No. 5, pp. 326-332).—Some details are given of associations, so far as observed, between hymenomycetous fungi and woody forest plants of various groups having ectotrophic but not endotrophic mycorrhiza.

Studies in the physiology of the fungi.—III, Physical properties of wood in relation to decay induced by Lenzites sæpiaria, S. M. Zeller (Ann. Missouri Bol. Gard., 4 (1917), No. 2, pp. 93-164, pls. 16, flg. 1).—The author follows up the previous report (E. S. R., 37, p. 129) with an account of preliminary experiments regarding the effects of L. sæpiaria on wood of Pinus palustris, P. echinata, and P. tæda, including a review of observation and opinion by others.

He concludes that resin is no safe or practical index of the durability of the three species of yellow pine investigated, except as its presence tends to exclude moisture, which is favorable to the fungi. High specific gravity of the heartwood, on the other hand, materially increases resistance to these fungi on all these pines. Specific gravity can be somewhat reliably estimated from the proportion of the summer wood to the spring wood. The width of the growth rings furnishes a further index of durability, which is greater in case of the narrower rings. Age, or distance from the central pith, shows no relation to dura-

bility up to 8 in. in radius. Sapwood decays irrespective of resin content, specific gravity, width of annual rings, or species.

The practical conclusion drawn is that specifications for great durability should be based on a judicious combination of high specific gravity, large number of rings per inch, and small percentage of sapwood present. The more durable timber is that showing broad bands of summer wood and narrow bands of spring wood as seen in the cross section.

Studies in the physiology of the fungi.—IV, The growth of certain fungi in plant decoctions, preliminary account, B. M. Duggar, J. W. Sever, and H. Schmitz (Ann. Missouri Bot. Gard., 4 (1917), No. 2, pp. 165-173, figs. 4).— Employing standardized decoctions, with or without additions as given, the authors have made a study of fungi with somewhat different habits of growth, employing for this purpose Macrosporium commune, Aspergillus niger, Glomerella (Glæsporium) gossypii, and Penicillium expansum. The results from each fungus are plotted and discussed.

The addition of sugar, nitrate, and phosphate gave in every case, except with Glomerella on bean decoction, an increase in growth over the addition of sugar alone. The next highest growth was obtained in most cases when sugar and nitrate were added. The changes produced in the hydrogen ion concentrations due to the growth of the fungi are also indicated.

Microorganisms in silage, G. M. Reed and Lena Barber (Missouri Sta. Bul. 147 (1917), p. 29).—Twenty-two different species of fungi are reported to have been identified from 15 samples of moldy silage. Penicillium italicum was the species most commonly found, while P. roquefortii, Mucor circinelloides, Rhizopus nigricans, and Oidium lactis were found in the order named. All of these fungi were isolated from silage that had been reported as injurious to stock as well as from silage that was entirely harmless. No evidence was obtained indicating clearly the connection of Aspergillus fumigatus with stock poisoning from moldy silage.

#### FIELD CROPS.

General agriculture, P. DIFFLOTH (Agriculture Générale. Paris: J. B. Baillière & Sons, 1917, vol. 2, 4. ed. rev. and enl., pp. 552, figs. 276).—A revised and enlarged edition of the work by the same author, previously noted (E. S. R., 14. p. 1032).

Agronomical investigations [at the Guam Experiment Station, 1916], A. C. Hartenbower (Guam Sta. Rpt. 1916, pp. 6-25, pls. 4).—This reports the continuation of work previously noted (E. S. R., 35, p. 829), including improvement work with corn and field tests with cotton, rice, tobacco, leguminous forage crops, Kafir corn, feterita, milo maize, and grasses.

Seedings of the Yellow Dent and Chisholm varieties of corn from Texas failed to set ears, while a white variety from Hawaii produced a few small inferior ears.

In 1915 Gila, an Egyptian cotton, and Columbia and Covington-Toole, Upland types, were heavily pruned and left in the plats to study the ration crops produced. Yields of seed cotton were secured which amounted to 301, 1,137, and 1,012 lbs. per acre, respectively. The highest yielding variety for both the first and second 1916 crops was Hartsville, with 1,820 and 1,754 lbs. of seed cotton per acre. Sea Island and Caravonica have proved unsatisfactory in all tests to date. Cotton growing throughout the island is briefly noted, and the following general conclusions drawn from accumulated data of cotton experiments: Cotton planting about May 1 is deemed unprofitable, as the ground is so occupied that the production of any other crop that year is prohibited, and because

the crop does not mature sufficiently early the next dry season to produce a ration crop that season. Cotton planted June 22 was completely harvested only 3.5 weeks before that planted December 7 following, the later crop maturing more uniformly and producing a higher quality ration crop. Cultivation during the rainy season proved impossible and weed control through the use of an arsenical spray difficult because of almost daily rains. The June planting required eight pickings, extending over 3.5 months, while the later planting required only three pickings, extending over but 3.5 weeks. Plantings made at the end of the dry season were of low grade and weak fiber as compared with the December plantings. The ration crop referred to required two seasons for its production.

Results obtained with Egyptian cotton in 1916 did not compare favorably with those secured in 1915, the difference being attributed to the date of planting and the source of the seed, the 1915 crop having been grown from Hawaii seed planted December 19, while the 1916 crop was grown from Arizona seed planted December 27—too late for seed from this source.

The native methods of rice growing are briefly described and fertilizer experiments with rice reported. The highest yield, 1,087 lbs. of rough rice per acre, was secured from an application of 95 lbs. of sulphate of potash. The untreated check yielded 259 lbs. With acid phosphate and nitrate of soda used alone the yield was 674 and 652 lbs. of rough rice per acre, respectively, while with a complete fertilizer it was 783 lbs. In variety tests, Hawaiian Gold Seed yielded 122 lbs., See Miu 704 lbs., and Porto Rico 105 lbs. The two native rice plats yielded 364 and 324 lbs., respectively. The imported varieties headed out about three weeks earlier than did the native rice. The native rice and Hawaiian Gold Seed lodged badly, while the other two varieties showed very little lodging.

Limited tests with alfalfa indicated that it is adapted to Guam conditions, although the results of an entire rainy season are deemed necessary for determination of its real value. Peruvian alfalfa has given the best results to date.

Tobacco investigations included variety and fertilizer tests and studies on the effects of shading and of lead arsenate treatment for the control of Heliothis obsoleta. The highest yield per plant from the unshaded plats was 11.14 oz. from White Burley with fertilization, and the lowest yield 3.5 oz. from Connecticut Broadleaf without fertilization. The average yield per plant for fertilized and unfertilized plats was: Oronoco 7.2 oz., White Burley 9.7 oz., Connecticut Broadleaf 5.8 oz., and Connecticut-Havana 5.2 oz. Shaded plants of White Burley and Oronoco gave an average yield of 48.6 per cent less tobacco per plant than unshaded plants on the same plats. An increased yield of 7.4 per cent was obtained with lead arsenate treatment. The unshaded plants gave an average increased yield of 21.88 per cent with fertilizers and the shaded plants an average increase of 10.1 per cent.

Soil inoculation tests with cowpeas gave yields of 885 and 808 lbs. of grainper acre, respectively, for inoculated and uninoculated fields, and 15,125 and 9,790 lbs., respectively, of green forage. Plantings of cowpeas on a lowland field yielded at the rate of 4.01 bu. of grain and 4,099 lbs. of green vines per acre. Other leguminous forage crops tested included soy beans, pigeon peas, jack beans, and velvet beans, the latter being deemed an especially valuable grain and cover crop for Guam. In variety tests with velvet beans, the Florida variety appeared to be best for grain production, yielding at the rate of 14.3 bu. of grain and 7.3 tons of green forage per acre in 1916 from plantings made in June, 1915. Guam-grown Florida velvet beans yielded 11.4 bu. per acre as compared with a yield of 9.5 bu. from imported Florida seed.

Field tests with Kafir corn, feterita, and mile maize are reported, and the value of the first two as soiling or grain crops indicated. Yields of forage amounting to 22,700 lbs. of feterita and 12,501 lbs. of Kafir corn per acre were secured on lowland in 1915. Successive cuttings of feterita stubble yielded 19.199, 4.612, and 11.416 lbs. of stover or fodder for the second, third, and fourth cuttings, respectively, with grain yields of 10.8 and 9.8 bu. per acre for the third and fourth cuttings. Plantings of feterita, mile maize, and Kafir corn on relatively high but fairly fertile land on November 20 gave average yields of 11.4, 9.3, and 13.2 bu. per acre, respectively, while plantings made in the same field on December 10 gave average yields of 7.8, 6.8, and 9.1 bu. per acre, respectively. Seedings made January 10 on heavy lowland soil yielded 23.56 bu. with black-hulled Kafir corn, 18.18 bu. with feterita, and 15.7 bu. with dwarf mile maize, the yields of green stover amounting to 7,995, 8.038, and 5,628 lbs. per acre, respectively. Counts of suckers and side branches showed an average of 3 suckers and 2 side branches per plant for feterita, 1 sucker and 1 side branch for milo maize, and only occasional side branches or suckers for Kafir corn. Approximately 25 per cent of the feterita heads were in the flowering stage when harvested, while Kafir corn and milo maize were quite uniform in maturity and in height of plant.

In the renovation of Para grass fields the best results were secured from the use of barnyard manure, when six cuttings were obtained yielding 65,604 lbs. of green forage per acre. A mowing of Para grass was scattered in furrows about 3 ft. apart and covered with soil for comparison with the usual propagation method of setting out roots. The estimated cost of the planting, exclusive of plowing, was \$3.60 per acre as compared with \$10 per acre for the old method. The grass attained an average height of 3 ft. at the end of six weeks, while approximately four months was required by the former system to attain sufficient growth for pasture. The new method is deemed especially desirable because it permits planting before the regular rains start, thereby providing pasture and a soiling crep during the rainy season.

The data from numerous tests with Paspalum dilatatum has led to the following general conclusions regarding the adaptability and planting of this grass: P. dilatatum on relatively high land has a value of fully one-half of that planted on low land during the rainy season. Large divisions of roots in plantings set not more than 2 ft. apart each way were found to be advisable even on low land for a thick turf and a quick pasture. Deep preparation of the soil before planting and careful weeding after planting are deemed essential for the best results. Live stock should not be pastured on the grass until four months after planting under ideal conditions, whereas on the higher lands fully six months should be allowed for the grass to become established.

Field tests with Guinea grass (Panicum maximum), millet, Elephantorrhiza elephantina, and Russian sunflower are briefly noted, the last-named crop alone being deemed sufficiently suited to Guam conditions for extended use.

[Report on field crops work at the Missouri Experiment Station] (Missouri Sta. Bul. 147 (1917), pp. 35-37, 49, 50, 51, 52-54, figs. 4).—This reports the continuation of work previously noted (E. S. R., 35, p. 825).

Corn investigations conducted by C. B. Hutchison, E. M. McDonald, and A. R. Evans included a continuation of variety tests at Columbia and on various fields throughout the State, the leading varieties remaining as previously reported (E. S. R., 36, p. 135), and cultural tests on the Maryville and Warrensburg fields. The highest corn yields at Maryville were secured for the first time from plantings made with a furrow opener, while single listing gave the next best yields, and surface planting the lowest yield. On the Warrensburg field little difference in yield was noted with corn planted on stalk land

plowed both deep and shallow in the spring and that which had been plowed both deep and shallow in the fall. Fall-plowed sod land gave slightly increased yields, while shallow fall plowing gave higher yields than deep fall plowing, both giving higher yields than spring plowing. Deep spring plowing gave much higher yields than shallow spring plowing.

Rate-of-planting tests and variety and breeding tests with wheat are reported. On the Shelbina field a seeding rate of 8 pk. per acre gave the highest yield, with the 7-pk. rate second, slightly decreased yields being recorded for the plats seeded at 5- and 6-pk. rates. The 10 leading wheat varieties at Columbia for the season of 1915 were Rudy, Lebanon, Harvest Queen, Fulcaster, Deitz, Pride of Genessee, Michigan Amber, Nigger, Pride of Indiana, and Gold Coin. In selection work the two best lines yielded 48.25 and 50.14 bu. per acre, respectively, while the original strains from which they were chosen yielded 31.45 bu. per acre.

Tests with winter oats were continued, some of the hardier strains giving promise for the future. An increased yield of 7.5 bu. per acre was obtained with oats sown on spring-plowed land as compared with the seedings on land disked and harrowed. Drilling in a seed bed prepared by disking and harrowing increased the yield over plats broadcasted and disked in by 8 bu. per acre. A seeding rate of 12 pk. per acre gave the best results. Variety tests with oats at Columbia gave an average yield of 44.3 bu. per acre for 24 varieties.

The improvement of winter barley varieties is reported as progressing favorably, while spring barley is deemed unsatisfactory at Columbia, due to the short growing season.

Cotton experiments, conducted by A. R. Evans, included variety and fertilizer tests. The five highest-yielding varieties are reported as Christopher Improved, Buck Long Staple, Hamilton Ounce Boll, Simpkin Prolific, and Ozier. The fertilizer tests included a comparison of applications of 200 lbs. of cottonseed meal, 200 lbs. of acid phosphate, and 3 tons of manure, resulting in increased yields of seed cotton of 470, 340, and 129 lbs. per acre, respectively, increases in no case deemed sufficient to pay the cost of the treatments.

E. M. McDonald conducted experiments on the influence of the spacing of rows of wheat and oats upon the yield and quality of grain. The 1915 oat crop was sown in rows, 3, 6, 8, and 12 in. apart, the 12-in. planting giving the highest yield, amounting to about 10 per cent more than the yield from the 6-in. planting. The 8- and 12-in. plantings of wheat were expected to yield from 10 to 25 per cent more than the 3- and 6-in. plantings in 1916.

This year completed the twenty-seventh year's work on crop rotation experiments conducted by M. F. Miller and R. R. Hudelson. The unmanured corn plat yielded 38 bu. per acre as compared with a yield of 45.7 bu. for the manured plat. The average yield for the untreated plat for the last six years was 11.14 bu. and for the treated plat 28.52 bu. per acre. The relatively high yield of the last year is attributed to the effect of sufficient rainfall. A complete fertilizer of 3 per cent nitrogen, 10 per cent phosphorus, and 4 per cent potash gave the highest yield of wheat for all treatments.

Experiments on the associated growth of corn and cowpeas resulted in higher yields of corn grown without cowpeas than when grown with them in the row or between the rows. A slight decrease in the nitrogen content of the corn and stover was noted where cowpeas were grown in the row. Determinations of the nitrates in the soil showed that cowpeas grown alone exhausted the supply of available nitrates as much as corn, indicating that the corn secured no nitrogen from the cowpeas. A pronounced physiological effect

of the association of these two crops was observed in the green appearance of the corn foliage late in the season where cowpeas were grown either in the row or between the rows, but has not yet been explained.

Experiments to determine the effect of handling cowpea land in various ways on the wheat crop following indicated that land into which the cowpeas have been worked gave better wheat yields than land receiving no cowpeas or land from which cowpeas have been cut. Little evidence has been secured to show any deleterious effect of cowpeas on the following wheat crop.

A study of the factors influencing the development of the maize plant, by M. F. Miller and F. L. Duley, again demonstrated that the middle third of the growing period (from time of laying-by to time of silking) was the most critical from the standpoint of both moisture and nutrient supplies. The water requirement of the plant was found not to be greatly influenced by the variations in the supply during the growing period, but to vary greatly with different seasons. The optimum water supply during 1915 gave a weight of ears equal to 36.9 per cent of the total weight of the plant, while the minimum moisture supply gave an ear weight of 17.9 per cent of the total. An optimum supply of plant food gave grain representing 35.8 per cent of the total, while a minimum supply gave a grain weight of only 1.9 per cent of the total.

[Field crops], F. Watts (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Vincent, 1915-16, pp. 5-7, 8-11, 13-15).—Brief notes are given on the results of cotton selections based on the mean maximum length of fiber, percentage of available fiber, average weight of seed, and percentage of lint to seed. Further cotton investigations included studies with crinkled dwarf rogues, inheritance of the number of teeth in the bracts of cotton, resistance to leaf-blister mite (Eriophyes gossypii) in budded cottons and in cotton hybrids, Brazilian cotton, and fertilizer tests with Sea Island cotton.

Attempts to improve the native corn varieties through selection are reported along two lines, first, to produce uniform yellow corn, and second, to increase the size of grain and amount of grain per ear.

The twenty-sixth year of crop experiments, B. R. LARSEN, A. HERSTADS, H. Foss, and K. Vik (Aarsber. Norges Landbr. Höiskoles Akervekstforsök, 26 (1914-15), pp. 3-65, flys. 5).—The extension of cooperative field crop tests in 1914 is discussed, and the results of several experiments are reported.

In experiments conducted for five years, potatoes planted about May 15 gave on the average a higher yield of tubers and a greater percentage of total production of dry matter than potatoes planted earlier or later. Plantings made about May 7, however, produced the largest tubers. Variations in yearly results were brought about by weather conditions. The late and medium late varieties proved better adapted to early planting than early or medium early sorts. It was found that under the prevailing conditions there was no advantage in planting potatoes, especially medium early varieties, before the soil at 25 cm. (10 in.) under the surface had reached a temperature of from 7 to 8° C. (44.6 to 46.4° F.). The date of planting seemed to have had no influence on the prevalence of dry rot.

Experiments on the influence of subsoiling to the depth of about 16 in. on soil consisting of a mixture of clay, sand, and gravel, and of a good moisture-holding capacity, with a subsoil of a clayey character but not very hard, were conducted for six years. The crops grown were turnips, potatoes, peas, spring wheat, and oats. The average results with all these crops showed an increase in yield from subsoiling, the largest increase in value being obtained with peas. The average results further indicated that the work had been done at a profit.

The results secured in an eight-year test of level and ridge culture of root crops indicated that the germination of the seed and the early growth of the

plants, especially during dry weather, is best with level culture, and that on good soil well worked and under favorable moisture conditions the differences in yield under these methods of culture are comparatively small.

Experiments with leguminous green forage crops on poor soils showed the value of adding field peas, vetches, and other leguminous plants to mixtures of forage crops for the purpose of increasing the yield of green forage and of grain and of improving their quality.

Report on culture experiments at the Norwegian Agricultural High School, 1914–15, S. Hasund and P. Borgedal (Ber. Norges. Landbr. Höiskoles Jordkltr. Forsök, 1914–15, pp. 1–22, 31–54).—The extension of cooperative field crop experiments in 1915 is pointed out, and the results of a number of these experiments are reported.

The average results of 81 cooperative fertilizer tests with nitrate of soda and sulphate of ammonia showed that the unit of nitrogen in sulphate of ammonia represented from 80 to 90 per cent of the value of the unit in nitrate of soda. In other cooperative tests the action of lime was found quite marked the first year on soil either unfertilized or fertilized with barnyard manure, while on soil receiving commercial fertilizers the effect of lime was unimportant the first year but much more striking the second and third years. In a cooperative series of 67 tests with lime, potatoes were not found benefited by its use, while meadows, as shown by 4-year experiments, gave an increase of 5.6 per cent in the yield of hay and barley fields of 4.4 per cent in the yield of grain as apparently due to lime treatment. A larger increase from liming was secured with unfertilized than with fertilized crops of barley.

Cooperative subsoiling tests in connection with the culture of different crops gave varied results and did not allow drawing general conclusions.

[Experiments with field crops], A. SJÖSTRÖM (Red. Ultuna Landtbr. Inst. [Sweden], 1915, pp. 41-52).—The results of cultural and variety tests with cereals and root crops are briefly reported. Petkus rye sown at three different rates gave practically the same yields of grain and straw from the three different seedings. The differences in yield resulting from sowing Hannchen barley on the first, fifth, and twentieth of May, as well as from pulverizing the soil to depths of 3, 5, and 7 cm. (1.2, 2, and 2.8 in.), were also insignificant.

In a test of soiling crop mixtures the best yield in the green forage cut July 22 of dry matter and nitrogen, 4.6 tons and 83 kg. per hectare (4.1 tons and 73.8 lbs. per acre) respectively, was secured from a seed mixture consisting of 120 kg. of oats, 175 kg. of field peas, and 40 kg. of vetch per hectare. Analyses made of a part of the crop allowed to ripen and harvested September 8 showed that the dry-matter content had almost doubled since July 22.

In another experiment Petkus rye harvested and analyzed at weekly intervals from June 1 to July 7 continued to increase in the yield of green forage until June 22. The dry-matter production continued to increase and at the close of the test was found to be four times as great as at the beginning, the average weekly increase being 940 kg. per hectare. The ash and nitrogen content continued to increase up to June 22.

Crops of a seed mixture consisting of 110 kg. of oats and 160 kg. of vetch per hectare and harvested weekly from July 7 to August 17 showed a continued increase in dry-matter during the period, with the exception of the last two weeks, when this factor remained constant. The percentage of vetch in the yield of the crop mixture increased from 23 to 50.1 per cent during the experiment.

Turnips, swedes, and field beets grown in comparison produced 85.8, 70.3, and 62.2 tons of roots per hectare, respectively. The average weight per root was 1.17 kg. for the turnips, 1 kg. for the swedes, and 0.69 kg. for the field

beets. The percentage of dry matter was highest in the field beets and lowest in the turnips. On October 13 the yields of dry matter per hectare were 8.58, 7.60, and 8.24 tons, and on November 10, 7.93, 8.28, and 8.18 tons for the turnips, swedes, and field beets, respectively. During the period of maximum growth, or from the middle of August to the middle of September, the crops produced over a ton of dry matter per hectare per week. Immediately after this period the production of dry matter fell to 0.5 ton, and a little later to 0.3 ton per hectare per week, while after October 13 no further production of dry matter was perceptible. Analyses of the forage made at various intervals from August 4 to October 13 indicated that the more rapid formation of dry matter took place in the first half of September, while the greater percentage of water was found prior to September 1.

The results of planting these root crops at different distances were in favor of planting in rows 60 cm. apart with the plants 25 cm. apart in the row, or 1,500 sq. cm. (132 sq. in.) of space per plant. These results were influenced to a certain extent by a poorer stand on the closer planted plats.

In a variety test Ostersundom turnip outyielded Bortfeld and Yellow Tankard, and Red Eckendorf field beets produced a higher yield than Barres Halflong. Satisfactory yields of a variety of swedes and of sugar beets are reported.

[Field crops], B. C. Burt (Rpt. Cauenpore [India] Agr. Sta., 1916, pp. 2-30).— This reports work at the Cawenpore experiment station (E. S. R., 31, p. 732) for the year ended June 30, 1916.

Notes are given on fertilizer experiments with wheat, and green manure tests and cultural experiments with wheat, cotton, gram, sugar cane, millet, pigeon peas, tobacco, barley, flax, and peanuts. Other experiments reported included deep v. shallow sowing for maize, maize and peanuts as a mixed crop, tests of different spacings with American cotton, rotation tests, and fodder crop experiments.

[Field crops], A. C. MacDonald (Dept. Agr. Brit. East Africa Ann. Rpt. 1913-14, pp. 191, pl. 1; 1914-15, pp. 145).—These reports continue work previously noted (E. S. R., 26, p. 793). Brief notes are given on the production of sisal, cotton, flax, corn, wheat, tobacco, and certain tropical plants in British East Africa, with supplementary reports from the government experimental farms at Kibos, Nairobi, and Kabete.

The advancement of the agricultural industries and of stock breeding in the Protectorate is summarized for the past seven years.

Cultural experiments conducted in Denmark with different mixtures of the seeds of forage plants. E. Lindhard (Tidsskr. Plantcavl, 22 (1915), No. 4, pp. 553-713, figs. 2; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 2, pp. 224, 225).—The author discusses the results obtained in a series of experiments with mixtures of seed of forage plants covering a period of twelve years, 1900 to 1912. The data are presented in tabular form. A mixture recommended by Nielsen and composed of the following ingredients per acre was used as a basis for comparison: Early red clover 6.4 lbs., Trifolium hybridum 1.8 lbs., T. repens 0.3 lb., Agropyron repens 3.2 lbs., Avena fatua 3.2 lbs., Phleum pratense 1.8 lbs., Festuca pratensis 1.1 lbs., Lolium perenne 1.8 lbs., and L. italicum 1.6 lbs.

A summary is given of the results obtained with ten other Gramineæ-Leguminosæ combinations. These together corresponded to the most varied cultural conditions, and, when used according to their individual adaptations, gave much better results than the Nielsen mixture.

Pollination and fertilization studies with grasses and legumes at the Tystofte Experiment Station, H. N. Francsen (Tidsskr. Planteavl, 23 (1916), No. 3, pp. 442-486, figs. 6).—The studies described were conducted with orchard

grass, tall oat grass, meadow fescue, English rye grass, Italian rye grass, timothy, meadow foxtail, *Poa fertilis*, field brome grass (*Bromus arvensis*), red clover, bird-foot clover, alfalfa, and yellow trefoil. In addition to the data secured the results obtained by other investigators are briefly reported.

Pollination experiments conducted with orchard grass for several years indicated that the species, while generally cross-pollinated, produced seed to some extent under self-fertilization. It was found that individual plants show considerable variation with reference to self-fertility. Similar experiments, but on a smaller scale, showed that tall oat grass under ordinary conditions is predominantly cross-pollinated. Pollination experiments with meadow fescue gave results very much the same as those secured with orchard grass. The two species of rye grass proved chasmogamous. In a series of pollination studies with timothy the plants behaved much like those of the foregoing species, but the results also indicated that types comparatively high in fertility when close-pollinated may be isolated.

Meadow foxtail proved to be generally cross-pollinated and did not seem to be lower in fertility when isolated than the species above mentioned. *P. fertilis* under ordinary conditions was found to be cross-pollinated, but when isolated close-pollination resulted in complete fertilization, and under unfavorable weather conditions during blossoming self-fertilization also took place. While field brome grass gave complete fertilization with pollen from the same plant, cross-pollination predominated when the weather conditions were favorable.

The results with red clover indicated the practically complete self-sterility of the plant. With reference to bird-foot clover it was concluded that cross-pollination is necessary for seed production and that pollination is dependent upon the action of insects.

In the case of alfalfa natural self-pollination produced some seed but artificial self-fertilization was much more effective in this regard, while artificial cross-pollination resulted in twice the number of seeds secured from artificially self-pollinated plants. The author discusses the possible relation of climate as a factor in this connection in addition to insects as pollinating agents.

Yellow trefoil showed a certain degree of self-fertility. In all the experiments conducted with this plant the blossoms of isolated individuals opened automatically.

Experiments with bird-foot clover and alfalfa in grass mixtures, E. Lindhard (Tidsskr. Planteavl, 23 (1916), No. 4, pp. 605-622, figs. 2).—The experiments described were conducted at Tystofte from 1910 to 1913. The mixtures used per töndeland (1.36 acres) in one series consisted of 8, 12, or 16 lbs. of bird-foot clover and varying quantities of orchard grass, tall oat grass, timothy, and Poa fertilis, the smaller quantities of grass seed being used with the larger quantities of bird-foot clover seed and vice versa. Where bird-foot clover was sown alone it was used at the rate of 20 lbs. per töndeland. The average yields of hay per töndeland for the three different quantities of seed for each mixture were as follows: Orchard grass 110, tall oat grass 140, timothy 120. P. fertilis 121, and bird-foot clover alone 125 cwt. The quantity of bird-foot clover in the hay of the different mixtures and the pure seeding was 36, 30, 43, 58, and 78 per cent, respectively.

In a second series of experiments 12 or 20 lbs. of alfalfa seed per töndeland was sown in a mixture of the different quantities of the grasses mentioned above. For the pure seeding of alfalfa 30 lbs. of seed per töndeland was used. The average yields of hay for the unit area for the two different quantities of seed for each mixture were as follows: Orchard grass 156, tall out grass 178. timothy 171, *P. fertilis* 161, and the pure seeding of alfalfa 159 cwt. The proportion of alfalfa in the hay from these different seedings was 50, 47, 57, 74,

and 89 per cent, respectively. The detailed results of the experiments are given in tables.

On the germinability of rice (Oryza sativa) and corn (Zea mays) in relation to temperature and humidity, Anna Da Fano (Atti Ist. Bot. R. Univ. Pavia, 2. ser., 16 (1916), pp. 17-39).—This paper reports experiments with five varieties of rice and three varieties of corn in a study of the effect upon germination of varying the temperature, the loss of moisture in the seed during exposure to the various temperatures, and the percentage of moisture in the seed during germination. The plan of the experiment included the exposure of the seed of the different varieties for from one to three hours, at temperatures of 30, 40, 50, 60, 70, and 80° C., and for one hour at a temperature of 90°. The seeds were also germinated at the temperature of the surrounding air, approximately 23°. The data are presented in tabular form and discussed at some length.

The author concludes that in *O. sativa* the maximum germination was obtained after exposure of the seed for three hours at 30°, except with the Ranghino variety, which attained its maximum germination after two hours exposure at 40°, and the germination of the different varieties varying between 84 and 88 per cent. The minimum germination observed occurred with exposure for three hours at 80°, and varied between 18 and 24 per cent, while exposure for one hour at 90° entirely destroyed the power of germination. The maximum moisture content of the seed for successful germination did not correspond in any way to the maximum moisture content of the seed. The quantity of moisture best suited for germination in *O. sativa* apparently lies between the limits of 9.5 and 12.5 per cent, figures which correspond to the moisture content present at the maximum and minimum germination of the seed.

The results obtained with Z, mays were analogous to those noted above. Maximum germination was observed after exposure of the seed for two hours at  $40^{\circ}$ , varying between 93 and 95 per cent. The minimum germination occurred after exposure for three hours at  $70^{\circ}$ , while exposure for one hour or longer at  $80^{\circ}$  resulted in loss of germinability. As in O, sativa, maximum and minimum germination did not correspond to maximum and minimum moisture content of the seed, but to an intermediate value.

Wheat and rye production in Iowa, W. R. HECHLER (lova Sta. Circ. 37 (1917), pp. 8, flgs. 3).—Recommendations are made for increased production of winter and spring wheat and winter rye in Iowa.

Plants growing on moor soils as a source of fiber, and the use of sphagnum in making bandages, H. von Feilitzen (Svenska Mosskkulturför. Tidakr., 31 (1917), No. 1, pp. 96-109, pls. 2, figs. 4).—This article discusses the value of Eriophorum vaginatum as a source of fiber for use in the textile industries and reviews briefly experimental and commercial work in this direction. The results of an experiment on the capacity for water absorption of air-dry fiber samples of E. vaginatum, flax, jute, cotton, and wool are reported. Brief notes are also given on the use of sphagnum moss in the preparation of bandages.

The origin and cultural history of the Danish strains of Barres field beet, L. Helweg (Tidsskr. Planteavl., 23 (1916), No. 2, pp. 289-339, figs. 20).—An article discussing briefly the origin of the field beet and its development from the wild species Beta maritima. The early cultivated forms are briefly noted and the more important varieties grown in Denmark at the present time are described.

In reviewing the history of the Barres field beet in Denmark it is pointed out that this variety constituted 21.2 per cent of the field beets grown in 1884 as compared with 88.4 per cent in 1915. The area devoted to the variety in 1915 was approximately 270,000 acres. The history of different strains of

Barres field beet now recognized in Denmark is briefly traced, and five strains, known as Næsgaard, Sludstrup, Rosted, Ferritslev, and Lille Taarøje, are described in detail with reference to form, color, top, ease of lifting, yield, dry matter content, and uniformity.

Genetical studies of variegated pericarp in maize, R. A. EMERSON (Genetics, 2 (1917), No. 1, pp. 1-35, flgs. 4).—This paper continues the study (E. S. R., 29, p. 333; 31, p. 135) of the inheritance of self-pattern in the pericarp of maize seeds, occurring as a sporophytic variation in variegated ears.

The later studies are in entire accord with those previously reported. The author formerly termed these changes somatic variations because they were first manifested in somatic cells. It was apparent from the beginning, however, that the factorial modification responsible for the visible change must often occur in meristematic cells from which later arise the germ cells as well as the somatic tissues of the pericarp, or even of the whole ear, and since such meristematic cells are germinal rather than somatic the variation is deemed to be better termed sporophytic.

Distinct variations in variegated ears of maize are described and new phases of the problem reported on. Most of the data presented were obtained in connection with heredity studies conducted at the Nebraska Experiment Station. The points studied were inheritance of sporophytic mutations from variegation to self-color, changes in type of variegation, reverse mutation—self-color to variegation, suggested explanation of the inheritance of certain sporophytic variations and the noninheritance of others, and the relation of variegation to unit-factor constancy.

"The seed ears used in the later studies have all been pollinated by colorless strains to avoid difficulties arising from the uncertainty of the purity of the pollen of variegated races. Self-colored, partly self-colored, variously variegated, and colorless seeds from variegated parent ears, thus pollinated, have given progenies containing a percentage of self-colored ears roughly proportional to the amount of self-color in the seeds planted, the maximum being approximately 50 per cent from self-colored and near-self seeds and the minimum none from colorless seeds. This has been equally true whether the parent ears have been homozygous or heterozygous for pericarp color. In the latter case, the self-colored ears have always occurred at the expense of variegated ears, never at the expense of colorless ones. Medium variegation has been found to be a simple Mendelian dominant to very light variegation. colored ears appearing in the progeny of F<sub>1</sub> ears of this cross have occurred at the expense of medium variegated ears rather than in the place of very light variegated ones. These facts are held to indicate that a genetical factor for variegation mutates to a factor for self-color, that only one of the duplex factors ordinarily so mutates, and that the factor for medium variegation mutates much more frequently than that for very light variegation."

The results obtained indicate that there is an inheritance of a light type of variegation arising as a sporophytic variation on medium variegated ears, although this has not been fully investigated. A sporophytic change in the type of variegation resulting in seeds with strongly colored crown spots associated with self-colored cob glumes is not inherited as regards either pericarp or glume color.

From one to five wholly or partly variegated seeds per ear have occurred on about two-thirds of the self-colored ears descended from two presumably unrelated variegated ears. Other related and unrelated cultures have not exhibited such exceptional seeds, and no variegated seeds, as far as known, ever occurred on a homozygous self-colored ear. One test indicates the inheritance of these presumably reverse mutations from self-color to variegation.

Histological examinations of the developing ovary and glumes and of the mature seed suggest a possible explanation for the color peculiarities of distinct somatic variations and for the inheritance of some and the noninheritance of others. The change from variegated to near-self seeds associated with little change in the color of the glumes is thought to occur only in subepidermal cells and consequently may be inherited, while the change from variegated to dark-crown variegated seeds accompanied by self-colored glumes is thought to be limited to the epidermal layers and hence incapable of inheritance.

These results are thought to favor the idea that single allelomorphic factors, rather than two or more closely linked factors, are responsible for the color pattern of both glumes and pericarp.

"The phenomena studied are held to have an important bearing on the question of unit-factor constancy. The existence of the series of at least nine or ten multiple allelomorphs to which variegation belongs indicates that a factor for pericarp color has mutated several times. Some of the factors of this series have not been observed to mutate, while others have mutated rarely, and still others many times. In fact, the principal difference between certain of the factors is thought to lie in their relative frequencies of mutation. It is suggested that data such as is here presented may help to explain the somewhat diverse results of selection experiments within pure lines, clonal lines, and the like."

Contribution to the study of cotton production and its future, J. V. NATTA MAGLIONE (Bol. Min. Agr. [Argentina], 20 (1916), No. 7-8, pp. 631-646, figs. 8).—This is a general discussion of cotton production in Argentina. The cost of production is estimated and presented in tabular form.

Studies on oat breeding.—V, The F<sub>1</sub> and F<sub>2</sub> generations on a cross between a naked and a hulled oat, J. Zinn and F. M. Surface (U. S. Dept. Agr., Jour. Agr. Research. 10 (1917), No. 6, pp. 293-312, pls. 9).—In continuing work at the Maine Experiment Station previously noted (E. S. R., 35, p. 831; 36, p. 834), the authors describe in detail a white naked oat, Avena sativa nuda var. inermis, and a black-hulled oat, A. sativa patula var. Victor, and the F<sub>1</sub> and F<sub>2</sub> generations of a cross between the two. The Victor oat was the female parent, and the naked oat the male parent, the F<sub>2</sub> progeny consisting of 11 hybrid grains, only 4 of which germinated when planted in 1915. The F<sub>2</sub> generation comprised \$54 plants, all of which, together with the F<sub>1</sub> generation, were examined for hull character, grain color, pubescence at the base of the grain, and inheritance of awns.

The hulled parent was characterized by the presence of firm flowering glumes which adhered closely to the caryopsis, biflorous spikelets, black color of glumes, strong awns, and a long but rather sparse pubescence at the sides of the base of the lower grain. The naked parent was characterized by loose, membranous flowering glumes which did not adhere to the caryopsis, multiflorous spikelets, white or light yellow glume color, almost total absence of awns, and the absence of pubescence. It is suggested that the absence of awns and of pubesence may be due to the inability of these characters to express themselves on the thin membranous glumes.

The F<sub>1</sub> generation is described as distinctly intermediate in most characters. In regard to the glumes, both naked and firmly-hulled grain and intermediate forms were found on the same panicle and even in the same spikelet. The spikelets near the top of the panicle were entirely naked, or nearly so, while those near the base of the panicle tended to be firmly hulled. A similar but less marked relation was observed between the spikelets near the tip and base of each whorl.

A large number of intermediate forms appeared in the  $F_2$  generation in addition to the two parental hulled types, four definite groups being distinguished. These intermediates contained all gradations from plants with perfectly hulled grain to the perfectly naked forms. The inheritance of the hulled characters presented a simple Mendelian ratio, giving 1 hulled, 2 intermediate, 1 naked. In grain color also there were three black plants to one white. It is shown that the genes for these two characters segregate independently of each other.

Multiflorous spikelets occurred only in connection with naked grain, plants with completely hulled grain bearing only biflorous spikelets.

The inheritance of pubescence at the base of the lower grain presented some difficulties, since it could not be manifested on plants with naked grain. By the use of a selected group of plants having hulled and intermediate grain, however, it was found that pubescence behaves as a bifactorial character, giving 15 pubescent plants to 1 without pubescence. Neither of these genes were linked with those for color. Available evidence indicates that one of these pubescent genes may come from the naked parent. Long and short pubescence at the base of the grain behaved as a monohybrid character and segregated independently of the other genes considered.

A remarkable feature of this cross was observed in the presence of pubescence at the base of the upper or second grain, no cultivated varieties of oats possessing this character. In this cross these forms occurred only on spikelets where the lower grain was naked or seminaked, and it is deemed probable that the presence of this pubescence was due to physiological disturbances caused by the presence of the naked lower grain.

The presence of awns was also affected by the nature of the glumes, a naked grain bearing only thin, weak awns. Considering only the hulled and intermediate types of grain, there appeared to be a simple 3:1 ratio between plants with medium strong to strong awns and those with weak awns.

[Potato culture], P. Weber and Kleberger (Jour. Landw., 64 (1916), No. 3, pp. 181-199).—The authors report experiments conducted on sandy, loamy, and clayey soils to test the effect of complete mineral fertilization, with especial reference to the nitrogen carrier, on the yield of potatoes and starch for each soil type. The nitrogenous fertilizers consisted of ammonium sulphate, calcium nitrate, ammonium nitrate, and liquid manure. The treatment of the plats was identical, and consisted of 352 lbs. of Thomas slag, 176 lbs. of 40 per cent potash salt, and either 176 lbs. of ammonium sulphate, 176 lbs. of calcium nitrate, 88 lbs. of ammonium nitrate, or 1,280 liters of liquid manure per acre. The soil type for each series of plats is described and the fertilizer treatment for each plat, together with the results obtained, are given in tabular form.

The results of the experiments indicate that nitrogen fertilization affects the yield of potatoes on the better loam and clay soils, while upon the sandy soils the potash and phosphorus fertilizers appeared to have the most pronounced effects. Satisfactory yields were not obtained on the heavier soils, however, with nitrogen alone. Of the nitrogen carriers tested, ammonium sulphate gave the best results on all soil types, although liquid manure gave very good results and is to be especially recommended at the present time.

The highest starch yields were obtained from the use of potash and phosphorus alone, liquid manure producing a slight and the remaining nitrogenous materials a decided reduction in the starch content.

The utilization of the nitrogen in the fertilizers did not always parallel the yields obtained. This was noticeable in the case of ammonium sulphate on clay soil, where only 90 per cent of the nitrogen was used, indicating that the nitrogen from the ammonium nitrate must have been used for the formation of

vegetative parts, such as the stem and leaves. The utilization of the potash and phosphorous fertilizers was materially influenced by the nature of the nitrogen carrier, the most complete utilization being obtained in connection with ammonium sulphate. The effect of liquid manure in this respect is favorable on loam soils.

The irrigation of potatoes, F. S. Harris (Utah Sta. Bul. 157 (1917), pp. 3-20, figs. 9).—Rather extensive irrigation experiments with potatoes conducted on the Greenville Experiment Farm are reported for the 5-year period of 1912 to 1916, inclusive. The life of the potato plant was divided into four stages, (1) when the vines were 4 in. high, (2) when the tubers began to form, (3) when the potatoes were in full bloom, and (4) when the potatoes were nearly ripe. One, 2½, 5, and 7½ in. applications of irrigation water were made weekly, and 5-in. applications at the different stages of growth. Important literature on the subject is reviewed and detailed tabular data presented.

A comparison of the yields of tubers and vines on plats receiving different quantities of irrigation water weekly showed the highest average yield of tubers for the 5 years, 337.1 bu., to have been obtained from a total of 12.8 in. applied 1 in. per week during the growing season. The maximum application of 96 in., or  $7\frac{1}{2}$  in. weekly, resulted in a lower average yield of tubers, 140.5 bu., than where no irrigation water was given, 153.3 bu., although the weight of air-dry vines was nearly doubled.

In a comparison of single applications at different stages of growth the lowest yield of tubers, 139 bu. per acre, resulted from an application made after planting and before the vines were up. The best results were secured from applications made when the plants were in full bloom and averaged 229 bu. per acre. Neither 10, 15, nor 20 in. applied in two, three, or four irrigations of 5 in. each gave results equal to regular weekly applications of 1 in. each. Late applications, as well as large quantities, of water increased the relative growth of the vines.

The average size of the tubers was larger where the water was applied weekly with 1-in. applications, both 5 and  $7\frac{1}{2}$  in. weekly applications producing smaller tubers than where no irrigation water was used. The tubers on plats receiving water at the third and fourth stage and those receiving it at all four stages averaged the same size and were larger than for any other treatment.

The average number of tubers per hill was largest with a 2½-in, application per week, while early applications appeared to be conducive to a large production of tubers per hill.

The average weight of the hills, determined by weighing 100 average hills from each plat, was highest with 1 in. and 2½ in. weekly irrigations, while a rapid decrease in weight per hill was noted with an increase in the amount of water applied. Applications made in the third stage proved most effective in increasing the weight per hill.

All irrigation treatments produced vines that were higher than those produced with no irrigation, but a comparison of the vine growth is deemed insufficient as an indication of the relative value of the different irrigation treatments. A wide variation in the color of the vines was noted for the different methods of irrigation and was considered a reliable means of determining the moisture requirements of potato plants.

The experiments are held to indicate the importance of an even supply of moisture during the middle portion of the life of the potato, after the tubers begin to form and before they begin to ripen.

Shallu, or "Egyptian wheat," a late-maturing variety of sorghum, B. E. ROTHGEB (U. S. Dept. Agr., Farmers' Bul. 827 (1917), pp. 8, figs. 3).—Shallu is

described as a late-maturing variety of sorghum exploited as Egyptian wheat, Mexican Desert wheat corn, and under many other local names.

The results obtained with shallu when grown under the dry-land conditions of the southern Great Plains are cited and compared with those secured from other grain sorghum varieties such as Dwarf milo maize, Dwarf Kafir corn. and feterita in variety, tests in Texas, Oklahoma, Kansas, and New Mexico.

Owing to its late maturity (125 to 140 days) shallu is subject to injury by drought and even under the most favorable dry-land conditions the yields are lower than those of Kafir corn and milo maize, while in unfavorable seasons it frequently fails entirely. Shallu often lodges badly and is not to be recommended where milo maize or Kafir corn can be grown successfully.

The irrigation of sugar beets, F. S. Harris (Utah Sta. Bul. 156 (1917), pp. 3-24, figs. 14).—Experiments with sugar beets are reported, showing the effect of different weekly irrigations and of standard 5-in. irrigations applied at certain periods in the growth of the plant on the yield of roots, yield of sugar, percentage of sugar and purity, and size and shape of beets. The life of the sugar-beet plant was divided into the following stages: (1) Just before thinning, (2) four weeks after thinning, (3) when the beets averaged 2 in. in diameter, and (4) when the beets were nearly ripe. The weekly irrigations consisted of applications of 1, 2.5, 5, and 7.5 in. of water, made during the regular irrigation season. Tabulated data are presented for the 5-year period of 1912-1916, inclusive, and the results compared graphically.

The highest average yield of beets on plats receiving weekly irrigations was secured from 1-in. applications, and amounted to 21.92 tons per acre, as compared with a yield of 12.98 tons without irrigation. When but one irrigation was given, that applied at the third stage of growth gave the highest average yield, 18.92 tons per acre. Where more than one application was made the highest average yield, 23.39 tons per acre, was secured from irrigations made at the first, third, and fourth stages of growth. Irrigation after planting but before the plants were up gave a yield of only 11.22 tons per acre. After the plants were up the least desirable time for irrigation was during the fourth stage of growth, when an average yield of but 15.09 tons was secured. Proportionately more tops were produced by the high and late irrigations than by opposite conditions.

Except where the water was applied quite late, the percentage of sugar and of purity was higher in the irrigated beets than in the nonirrigated. The highest average percentage of sugar was secured from a weekly application of 2.5 in. of water and amounted to 16.32 per cent. When one irrigation was given, the highest average percentage, 15.73 per cent, was obtained from an application made in the third stage of growth, while an average of 14.5 per cent was obtained from plats receiving no irrigation. The highest average purity was secured from weekly applications of 5 in. of water and amounted to 83.9 per cent, as compared with 78.4 per cent from nonirrigated plats and 83.2 per cent with 2.5 in. of water weekly.

The length of beets was not increased by delaying the time of application of the first irrigation, early irrigation apparently facilitating penetration of the roots into the soil. The average length of root from the nonirrigated plats was 10.6 in., while the longest roots were secured from the plats receiving applications of water during the first three stages of growth, and averaged 11.7 in. Weekly applications of 1 in. of water gave roots with an average length of 11.5 in.

Irrigation affected the size of the beets in about the same manner that it affected total yield. The highest average weight, 2 lbs., was secured from plats receiving 1 in. of water weekly, as compared with an average weight of 1.09 lbs.

from the nonirrigated plats. The percentage of forked beets bore no apparent relation to the amount of water used.

The author concludes that sugar beets do not require large quantities of irrigation water, provided it is properly applied, but that they are sensitive to the time of application.

The weeding of wheat, E. Rey (Jour. Agr. Prat., n. ser., 29 (1916), Nos. 19, pp. 324-326; 20, pp. 346-348; 23, pp. 392-394; 25, pp. 429, 430).—This is a general discussion of the beneficial effects obtained from weeding wheat. The author cites a number of authorities in support of his arguments, giving the results of several experiments and emphasizing the economic phases.

The effect of heating seeds upon the development of the plant; experiments made in Russia with wheat, S. J. Wordbiew (Khozūšistvo, 10 (1915), No. 47-48, pp. 1075-1083; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 4, pp. 527-530).—The author reports experiments with "Arnaoutka" (a mixture of different varieties) and Kubanka wheats, strains of Triticum durum, to determine the effect of relatively high temperatures upon the plant embryo. The seeds were planted in pots after exposure for 20 minutes to a temperature of 80° C. (176° F.). The pots received 60, 40, and 20 per cent of the amount of water required to saturate the soil. The results obtained are summarized in an appended table.

The author concludes that heating has a stimulating effect upon the embryo and promotes a tendency to xerophytic structure, shown in the reduced height of the plant, the decreased relative weight of the leaves, and the dimensions of the cells. Since xerophilous plants best withstand a lack of water, it can be assumed that where moisture is abundant, heating the seed produces no modification in the structure of the plant, but where it is limited, heated seeds produce plants so modified as to withstand drought.

Root-crop seeds.—Harvest and trade of 1915-16, L. Helweg (*Tidsskr. Planteavl*, 23 (1916), No. 3, pp. 487-518, fig. 2).—An article discussing at some length the yield and quality of turnip, field beet, rutabaga, and carrot seed secured in Denmark in 1915, including a review of a number of court decisions in settlement of cases arising in the root-crop seed trade.

Yellow rocket, a dangerous weed, E. A. Bessey (Michigan Sta. Spec. Bul. 80 (1917). pp. 3, 4).—Yellow rocket, winter cress, or herb barbara (Barbarea barbarea), said to have been introduced as an impurity in clover and grass seeds, is briefly described and methods of eradication recommended.

#### HORTICULTURE.

One thousand hints on vegetable gardening, MAE S. CEOY (New York and London: G. P. Putnam's Sons, 1917, pp. VII+275).—This work comprises practical hints arranged in short paragraphs on the culture of the common vegetables, fruits, and nuts, together with miscellaneous suggestions relating to gardening and garden equipment, planting tables, etc.

[Report of horticultural investigations], A. C. Habtenbower (Guam Sta. Rpt. 1916, pp. 26-38, pls. 2).—Notes are given on the acquisition and distribution of seeds and plants during the year, together with data on general fertilizer and cultural tests of beans, peppers, eggplants, radishes, carrots, muskmelons, cucumbers, watermelons, squash, okra, pumpkins, sweet corn, onions, and udo.

A test was started on August 1, 1915, to determine the longevity of vegetable seeds when stored in ground-glass top exhibition jars and when stored in cloth sacks in insect-proof wooden cabinet drawers. Germination tests were made at semimonthly intervals until the following June 15. The data as here pre-

sented in tabular form show a marked advantage in using closed jars as the time of storage increases.

Brief notes are given on the condition of fruit trees introduced at the station previous to July 1, 1914, and during 1915 and 1916. Tests of the inarching method of propagating mangoes resulted in a loss of 18 per cent of the plants. The size of fruit in the station lowland pineapple field was materially increased by providing good drainage. The station is to undertake work looking to the improvement of the coconut crop on the island.

[Progress report on horticultural investigations] (Missouri Sta. Bul. 147 (1917), pp. 40-43, 44-47).—In continuation of previous reports (E. S. R., 35, p. 837) concise statements are given of progress made along various lines of horticultural work during the year ended June 30, 1916.

Fruit nutrition studies in charge of J. C. Whitten and C. C. Wiggans were conducted with strawberries, peaches, and apples during the year. The work with strawberries was confined to the use of fertilizers containing phosphorus, since previous results from the use of potassium and nitrogen were negative. Acid phosphate applied directly to the row, either the current year or the previous year, caused a marked increase in yield, while bone meal even at the end of the second year caused no increase. The question has been raised as to whether or not the effect of the acid phosphate may not be wholly or in part due to the acid condition possibly resulting from its application rather than to the phosphorus it contains. Studies are to be conducted along this line.

In the nutrition experiments with peaches the trees receiving nitrogen over a period of years are markedly larger, more vigorous, and carry a greener foliage than those receiving no nitrogen. Also by far the greater effect in increasing yield has been shown on the nitrogen plants. During the last year the fruits on the trees fertilized with nitrogen were noticeably smaller in size, but not sufficiently so to injure the market quality, the larger number of peaches more than offsetting the reduction in size. The peaches seemed firmer and in better condition for long shipment.

The work with apples continued to show the superiority of nitrogen fertilizers on young trees, although the trees fertilized with nitrogen were more subject to blight. Blight was also found to be twice as prevalent on trees where cowpeas were grown and turned under the previous year as on plats where the trees were in timothy or alfalfa sod. Hence, it is concluded that where blight is destructive growers should use discretion in applying nitrogen fertilizer or in turning under leguminous crops. The results secured with fertilizers on older apple trees indicate in brief that the addition of fertilizer may or may not be profitable, depending on conditions in the individual orchard.

Among other investigations with fruits being conducted by J. C. Whitten work in breeding apples for late blooming habit was started. Planting tests of hardy fruit trees, such as the apple and pear, continued to show that fall planting causes uniformly much stronger growth than spring planting. During the last year late fall planting gave better results than early fall planting and late spring planting gave better results than early spring planting. The sour cherry profits more by fall planting, as compared with spring planting, than any other species that has been tested. The past year's results showed that approximately two-thirds of the spring-planted cherry trees died, while there was no loss among those planted in the fall. The surviving spring-planted trees made 25 per cent as much growth as the fall-planted trees.

Based on the yields secured from four crops, Ben Davis apple trees grown from fruit buds selected from a productive parent have shown no superiority over those selected from an unproductive parent. A similar experiment in straw

berry selection (E. S. R., 33, p. 236) covering a period of 10 years and now completed also gave negative results.

Self-fertility studies of fruits by J. C. Whitten and C. C. Wiggans confirm the previous assumption that certain commercial varieties of apples have a tendency to self-fertility. Varieties such as Delicious, Ingram, Ben Davis, Gano, and York appear to be capable of fertilizing their own flowers when planted in large blocks.

Observations made on fruit trees in connection with tillage studies by J. C. Whitten and C. C. Wiggans indicate that the formation of fruit buds is induced by highly concentrated sap and wood growth, and lack of fruitfulness is indicated by less concentrated sap. In the tillage studies the tree sap was found to be more concentrated in orchards where cultivation is not extensive and where apparently greater competition with sod crops exists. Sap studies are to be conducted for a number of years with the view of determining a possible correlation between sap concentration and tillage methods.

The studies of fruit-bud development of trees as influenced by treatments and previous crops, conducted by C. C. Wiggans, confirm the conclusion previously drawn that only a small percentage of the spurs blossoms two years in succession and even a smaller percentage matures fruit two years in succession. It was found in every case where tests were made that the concentration of cortex sap from bearing spurs was greater than that from non-bearing spurs, if the determination was made during or soon after the fruiting season. Leaf sap from nonbearing spurs shows a higher concentration than leaf sap from bearing spurs. The high concentration of cortex sap from bearing spurs appears to exist only while the spur has fruit on it. Later the bearing spur comes back to normal concentration. So far as observed, there is no correlation between the number of leaves on a spur and its fruit development. Spurs bearing two or more fruits show little or no difference in sap concentration from those bearing only one fruit.

Examination of buds in winter for forecasting probable bloom, as made by C. C. Wiggans, indicates that it is possible to forecast the probable bloom of apple trees. Further observations are being made with the view of developing methods of forecasting that may be used by the average grower.

Protection of fruit against late spring frosts, A. D. Beeleb (U. S. Dept. Com., Com. Rpts., No. 221 (1917), p. 1101).—A consular note on a new product, "agélarine" (antifrost), said to be a vegetable derivative compounded from the juices of certain plants. This material, it is claimed, has been successfully used for coating fruit trees, thereby retarding their blooming period without injuring the trees.

[Spray calendars] (New Jersey Stas. Circs. 75-79 (1917), pp. 2 each).—A series of circulars consisting of spray calendars for apples and quinces, pears, sweet cherries, plums, and peaches, as above numbered, respectively.

Blooming period of the apple in northwest Arkansas, W. H. Wicks (Arkansas Sta. Bul. 134 (1917), pp. 3-12, figs. 3).—This bulletin contains data collected in 1914, 1916, and 1917 to ascertain the blooming period of different varieties of apples. The work was limited to Washington and Benton Counties in northwest Arkansas. Records were kept by over 300 growers each year, in addition to records kept by the author.

A study of the data as a whole shows that the relative blooming period of varieties is not constant, that weather conditions preceding and during the blooming period exert an important influence on the earliness and length of the blooming period, and that varieties possess different degrees of susceptibility to climatic conditions. On certain slopes, elevations, and soils, and under cer-

tain methods of culture the same varieties will begin to bloom a few days earlier or later.

The varieties observed are classified according to time of blooming. A study of the data collected shows that the leading commercial varieties of the section, namely, Ben Davis, Jonathan, Winesap, Grimes, and Mammoth Black Twig, all blossom at about the same period, thus making it possible to secure the greatest benefit of cross-pollination, provided there is mutual affinity between them. Other varieties of less commercial importance also bloom during the same period with the leading varieties, and where bees are kept in or near the orchard the greatest benefit from cross-pollination is assured.

The apple grading and packing law enacted by the Delaware legislature, 1917 (Bul. Bd. Agr. Del., 6 (1917), No. 4, pp. 11-15).—The text of this law, which became effective on June 1, 1917, is here given in full.

Investigations and experimental work carried on in cherry orchards in Kent during the months of April and May, 1915-16, G. P. Bebry (Jour. Bd. Agr. [London], 24 (1917), No. 3, pp. 288-298).—Notes are given on varieties of cherries growing in Kent orchards, including information relative to their blooming period and relative sterility or fertility when grown alone and in admixture with other varieties. Some good pollenizers for the Early Rivers variety were determined by actual experiment.

A census of the peach crop of 1917 in West Virginia, compiled by W. H. Somers (W. Va. Dept. Agr. Bul. 26 (1917), pp. 24).—This comprises estimates for the 1917 season of the number of baskets of peaches in the various orchards in West Virginia.

Report on fertilizer experiments with cranberries, F. P. Schlatter (*Proc. Amer. Cranberry Growers' Assoc.*, 48 (1917), pp. 9-12).—A progress report on cooperative experiments being conducted under the direction of the New Jersey Experiment Stations (E. S. R., 36, p. 641).

As a result of the work conducted during the past five years the author recommends the use of acid phosphate, rock phosphate, and bone meal for mud bottoms and iron ore bottoms. For sandy or savanna bottoms and possibly for mud bottoms having a heavy coat of sand on top, nitrate of soda, dried blood, cottonseed meal, acid phosphate, basic slag, bone meal, and rock phosphate, either singly or in proper and judicious mixtures, may prove of value. Potash has apparently no value. The use of sulphate of ammonia as a source of nitrogen is not recommended.

Spoilage of cranberries after picking, C. L. Shear (*Proc. Amer. Cranberry Growers' Assoc.*, 48 (1917), pp. 6-9).—A paper on this subject outlining the cooperative investigations conducted by the U. S. Department of Agriculture in Massachusetts and New Jersey. The author briefly discusses spoilage due to fungus rots and premature death of the fruit caused by rapid ripening or suffocation.

First report on cacao selection in Assinan, G. Homburg and C. J. J. Van Hall (Meded. Proefstat. Midden-Java, No. 27 (1917), pp. 7).—A record is given of the yield of parent trees included in the selection study, together with notes on the condition of stock budded from these trees.

Additional observations on the citrus fruits in the Philippines, P. J. Wester (Philippine Agr. Rev. [English Ed.], 10 (1917), No. 2, pp. 104-115, pls. 7).—In continuation of a previous bulletin on citriculture in the Philippines (E. S. R., 30, p. 644), observations are given on a number of species that have fruited recently at the Lamao Experiment Station, including tabular data showing the degree of citrus canker affection in the station collection.

A contribution to the history of the mango in Florida, P. J. WESTER (Philippine Agr. Rev. [English Ed.], 10 (1917), No. 2, pp. 146-149, 18. 2).—This

contribution is based on the literature of the subject and on the data assembled by the author when connected with the subtropical garden in Miami, Fla.

The pistachio, R. Falci (Bol. R. Giard. Colon. Palermo, 3 (1916), No. 3-4, pp. 128-184, pls. 6, figs. 3).—This comprises the results of a study relative to the biology, varieties, and culture of the pistachio in Sicily. A number of plates are appended showing the nature of the foliage and nuts of different species, hybrids, and varieties.

Trees suitable for the farm and for ornamental purposes, W. E. Dowsert (*Rhodesia Agr. Jour.*, 14 (1917), No. 4, pp. 487-490, pls. 3).—A descriptive list is given of trees suitable for the farm and homestead in Rhodesia.

Plant materials of decorative gardening: The woody plants, W. TRELEASE (Urbana, Ill.: Author, 1917, pp. 204).—A pocket guide to the generic and usually the specific name of the hardy trees, shrubs, and woody climbers found cultivated in the eastern United States (except in the extreme South) or in northern Europe, exclusive of nurseries, botanical establishments, and pretentious estates. In the generic descriptions more attention is given to wood, bud, leaf-scar, foliage, and inflorescence than to the more transient details of flower and fruit on which botanical classification largely rests. The nomenclature is in accord with that used in the Standard Cyclopedia of Horticulture. Other commonly used names are added as synonyms.

Annuals and biennials, Gertrude Jekyll (New York: Charles Scribner's Sons. [1916], pp. XIV+174, pls. 44).—Part 1 of this volume discusses some ways of using annuals and biennials, raising annuals in greenhouse or frame, annuals and biennials for autumn sowing, annuals as edgings, color schemes with annuals, hedge-forming and climbing annuals, annuals in the rock garden, sweet scented annuals, and annuals and biennials for use as cut flowers. Part 2 comprises an alphabetical list, with description and culture, of the best annuals and biennials. In part 3 a chart of color and height together with selectious for various purposes and aspects are given.

Garden flowers of spring, ELLEN E. SHAW (Garden City, N. Y.: Doubleday, Page & Co., 1917, vol. 1, pp. 230, figs. 217).—This is the first of a series of four volumes constituting the Pocket Garden Library, edited by L. Barron. The present volume contains descriptions with illustrations in color of garden flowers of spring.

Garden flowers of summer, Ellen E. Shaw (Garden City, N. Y.: Doubleday, Page & Co., 1917, vol. 2, pp. 251, figs. 238).—A volume similar to the above describing garden flowers of summer.

Garden flowers of autumn, Ellen E. Shaw (Garden City, N. Y.: Doubleday, Page & Co., 1917, vol. 3, pp. 195, figs. 185).—A volume similar to the above describing garden flowers of autumn.

Flowers of winter, indoors and out, M. Free (Garden City, N. Y.: Doubleday, Page & Co., 1917, vol. 4, pp. 206, figs. 196).—A volume similar to the above describing flowers of winter, indoors and out.

The livable house.—Its garden, Ruth Dean (New York: Moffat Yard & Co., 1917, vol. 2, pp. XXI+174, figs. 107).—This is one of a series of volumes dealing with the home and its surroundings. The successive chapters discuss the grounds as a whole; general planting; the flower garden; spring planting, trees, shrubs, flowers, bulbs, tall planting, and pruning; and garden architecture.

How to make concrete garden furniture and accessories, edited by J. T. FALLON (New York: Robert M. McBride & Co., 1917, pp. XVIII+105, pls. 15, flgs. 33).—A treatise on the use of concrete in the garden. It discusses the selection and testing of material; how to proportion and mix the materials; making forms and placing the concrete; how to make garden walls, steps, and other simple utilities; how to make sundials, benches, swimming pools, bird baths,

lanterns, pottery, and water gardens; and making concrete garden frames and garden rollers.

#### FORESTRY.

General survey of Texas woodlands, including a study of the commercial possibilities of mesquite, J. H. Foster, H. B. Krausz, and A. H. Leidigh (Bul. Agr. and Mech. Col. Tex., 3. ser., 3 (1917), No. 9, pp. 47, figs. 20).—This comprises a general survey of forest and woodland conditions in Texas, including also a discussion of the geography, soil, and climate of the State. Data on a study of the commercial possibilities of mesquite, made by H. B. Krausz, are also given.

Forest resources of eastern Texas, J. H. Foster, H. B. Krausz, and G. W. Johnson (Bul. Agr. and Mech. Col. Tex., 3. ser., 3 (1917), No. 10, pp. 57, figs. 12).—Data are given on the forest resources, industries, and outputs by counties of the east Texas timber belt.

The Patagonian forests, M. ROTHKUGEL (Los Bosques Patagónicos. Buenos Aires: Min. Agr., 1916, pp. 207, pls. 23, flgs. 99).—This embraces the results of a reconnoissance of the forest regions of Patagonia. Information is given relative to the general distribution of the forests, distribution by species, data on density and yield from different stands, lumbering conditions and activities, and probable future distribution of commercial species. The more important species are considered in detail, and a number of maps are appended showing their distribution.

Timber estimating methods used in eastern North Carolina, H. R. KRINBILL (Biltmorean, 4 (1917), No. 2, pp. 13-21).—A descriptive account illustrating the application of these methods on various timber tracts.

Sixth annual report of the State forester to the governor for the year ended December 31, 1916, F. A. ELLIOTT (Ann. Rpt. State Forester Oreg., 6 (1916), pp. 20, fig. 1).—A report on forest fire protection work during the year ended December 31, 1916.

Forestry, J. A. VIQUESNEY (Bien. Rpt. Forest, Game and Fish Warden W. Va., 1915–16, pp. 39–89, pls. 4, flgs. 26).—A report of forest activities in West Virginia for the biennial period ended July 1, 1916, including a discussion of State and Federal fire protection, the character of the fire season, and the assistance rendered by private landowners, railroads, and rural mail carriers. A plan prepared by E. S. Bryant for fire protection by the State of West Virginia in cooperation with the southern West Virginia fire protective association is here included.

Law of the woods and yerbales (Ley de Bosques y Yerbales. Buenos Aires: Min. Agr. Nac., 1915, pp. 91, pls. 3).—This comprises the text of a proposed forest law for Argentina as presented to the National Congress, Buenos Aires, on September 30, 1915.

Amendments to the Central Provinces Forest Manual (third edition) (Nagpur, India: Govt., 1915-1917, pp. [67]).—This comprises various additions, substitutions, and corrections to the manual previously noted (E. S. R., 36, p. 843).

On the sun and shade leaves of some trees, T. Doi (Jour. Col. Sci. Imp. Univ. Tokyo, 40 (1917), Art. 1, pp. 37, pl. 1, figs. 4).—A contribution to the knowledge of leaf structure as influenced by light and shade, based on investigations of plants and trees growing in the botanic garden of the Imperial University of Tokyo.

The carob and its rational culture, G. Amico (Il Carrubo Coltivato Razionalmente. Catania: F. Battiato, 1916, pp. 103, fig. 1).—An account of the carob

(Coratonia siliqua) with reference to its distribution; botany; varieties; propagation; flowering, pollination, and fruiting; culture; commercial importance; and economic uses. The work has been written with special reference to the extension of carob culture in Italy.

The black wattle industry.—Acacia mollissima, A. decurrens var. mollis, T. R. Sim (So. African Jour. Sci., 13 (1917), No. 7, pp. 279-301).—A general and statistical account of the black wattle tanbark industry in Natal.

Catalogue of the wood specimens exhibited in the economic section, T. V. NABASINGA RAO (Madras: Govt. Museum, 1916, pp. VI+114).—A catalogue of the wood specimens exhibited in the Madras Government Museum, giving the common names of the wood, distribution, characteristics, and uses.

The grouping of ties for treatment, C. P. Winslow (*Proc. Amer. Wood Preservers' Assoc.*, 13 (1917), pp. 386-413, figs. 3).—A paper presented at the annual meeting of the American Wood Preservers' Association in New York City in January, 1917, and discussing the proper grouping for preservative treatment of woods used as railroad ties.

Paper and wood pulp industry, W. A. Ruff (Bur. of the Census [U. S.] Census of Manfr. 1914, Paper and Wood Pulp, pp. 19).—This comprises a summary of the principal statistics for the paper and wood pulp industry as a whole for 1914 and 1909, together with special statistics relating to materials, products, equipment, imports, and exports.

Forest products of Canada, 1916.—Pulpwood (Dept. Int. Canada, Forestry Branch Bul. 62B (1917), pp. 13, flgs. 7).—A statistical account of the pulpwood consumption in Canada in 1916. The Canadian mills consumed 1,764,912 cords valued at \$13,104,458, while 1,068,207 cords valued at \$6,866,669 were exported.

## DISEASES OF PLANTS.

New or interesting species of fungi, H. D. House (N. Y. State Mus. Bul. 188 (1916), pp. 29-58, pls. 4).—Among other fungi this list includes, as more or less parasitic on economic plants, the new species Cercospora caricis on Carex folliculata, Cercospora lathyri on Lathyrus maritimus, Glæosporium alnicola on Alnus rugosa, G. falcatum on Benzoin æstivale, G. hydrophylli on Hydrophyllum canadense, Phoma pectinata on Abies pectinata, Phyllosticta steironematis on Steironema ciliatum, Ramularia cichorii on Cichorium intybus, Scolescosporium coryli on Corylus americana, Septoria mollisia on Antennaria neodicica and A. canadensis, S. tenuis on Carex tenuis, Stagonospora convolvuli on Convolvulus sepium, and Dothidella vacciniicola on Vaccinium atrococcum; the newly named form Phoma bumeliæ (P. (Sphæropsis) maculans) on Bumelia; and the newly formed combination Septoglæum ochroleucum (Septoria ochroleuca) on Castanea dentata.

Texas parasitic fungi.—New species and amended descriptions, B. C. Tharp (Mycologia, 9 (1917), No. 2, pp. 105-124).—The pathogenic fungi described in this article, collected in 1914 to 1916 near Austin and in several points in east and northeast Texas, include, besides some previously known, the new species Ascochyta boerhaavia, Cercospora acalypharum, C. ammannia, C. apiifolia, C. arboria, C. bidentis, C. bliti, C. capitati, C. carolinensis, C. crythrinicola, C. ficina, C. helenii, C. hydrangeana, C. marrubii, C. mirabilis, C. modiola, C. nelumbonis, C. nigri, C. nyssa, C. piaropi, C. populicola, C. pulcherrima, C. regalis, C. rosigena, C. salviicola, C. texensis, C. tora, Colletotrichum cinnamoni, Coniothyrium rhois, C. ulmi, Exosporium liquidambaris, E. platanorum, B. phoradendri, Napicladium prosopodium, Phleospora ptelea, Phyllachora texana, Phyllosticia cephalanthi. P. euonymi, P. verbenicola, Ramularia acalypha, R. salviicola,

Septoria angularis, S. antirrhinorum, S. argemones, S. asterina, S. hicoria, S. urticaria, and S. wistaria; and the new varieties Cercospora euphorbiacola tragia, and C. pulcherrima minima.

Uredinales of Porto Rico based on collections by H. H. Whetzel and E. W. Olive, J. C. ARTHUR (Mycologia, 9 (1917), No. 2, pp. 55-104).—Following the collection of fungus material during the spring of 1916 by Whetzel and Olive and its systematic study by the author, 122 species of the Uredinales are listed. A number of these are regarded as new species or treated as new combinations, some being of more or less importance in connection with ornamental or useful plants. A list is given of species previously reported from Porto Rico.

A short-cycled Uromyces of North America, G. R. BISBY (Abs. in Phytopathology, 7 (1917), No. 1, p. 74).—It is claimed that there are only 11 species of short-cycled Uromyces found in North America and that these are parasitic upon six families of monocotyledons and dicotyledons.

A systematic and physiological study of rusts, G. M. Reed, C. R. Hursh, and W. E. Brentzel (Missouri Sta. Bul. 147 (1917), p. 28).—A report is given of tests under greenhouse conditions of 46 varieties of oats belonging to 9 species of Avena to determine their susceptibility to the crown rust of oats (Puccinia coronifera). Only one variety showed any degree of resistance and on this the rust developed to maturity. Additional tests were made with a number of species of grasses, and although the different grasses are known to be hosts of the rust P. coronifera, no infection was obtained by using uredospores from oats, this result indicating the existence of physiological races in this rust.

Notes are briefly reported on rust infection on varieties of wheat. With few exceptions, the varieties tested were all found badly infected with orange leaf rust (*P. triticina*).

A fundamental study of the physiological relation of the powdery mildews to their hosts, G. M. Reed (Missouri Sta. Bul. 147 (1917), p. 27).—The author summarizes the results of previous investigations (E. S. R., 35, p. 651) in which he described the relation of powdery mildew to varieties of Triticum and Avena. In addition to the data previously reported, it is stated that a large number of experiments have been conducted with varieties of barley in relation to barley mildew, most of the varieties tested proving quite susceptible.

Control of Phytophthora infestans in the floating gardens of Xochimilco, A. MADABIAGA and R. VILLABBEAL (Bol. Dir. Agr. [Mex.], 2 (1916), No. 2, pp. 55-57).—This is a discussion of local conditions affecting the success of cultivated plants in the floating gardens, more particularly the tomato, as affected by P. infestans, with suggestions for protection against that fungus.

Economic hosts of Sclerotinia libertiana in tidewater Virginia, J. A. Mc-CLINTOCK (Abs. in Phytopathology, 7 (1917), No. 1, p. 60).—In the warm, humid climate of tidewater Virginia, S. libertiana is said to be a serious parasite of lettuce, snap beans, tomatoes, winter-grown parsley, cauliflower, and eggplants.

A new strain of Puccinia graminis, E. C. STAKMAN and F. J. PIEMEISEL (Abs. in Phytopathology, 7 (1917), No. 1, p. 73).—The authors report a rust which behaves differently from any of the common biologic forms of P. graminis. This has recently been found on club wheat and a number of wild grasses, and is said to occur only west of the Rocky Mountains in Idaho and Washington, where it seems to take the place of ordinary P. graminis tritici.

Grain-smut investigation and control, G. M. Reed (Missouri Sta. Bul. 147 (1917), pp. 27, 28).—Inoculations with spores of Sphacelotheca sorghi were made on 22 varieties of sorghum, including broom corn, kaoliang, and Kafir corn, four of which, feterita, Jerusalem corn, dwarf milo maize, and milo maize,

remained free from infection, while all the others gave percentages of infection ranging from less than 1 to 31.

Inoculation experiments with bunt (*Tilletia factens*) on 15 common varieties of wheat gave infection in all cases, the amount ranging from 8.3 to 62.8 per cent. The effect of date of planting on amount of infection was also tested, planting being made from October 2 to October 30, and it was found that seed planted latest in the year gave the highest degree of infection.

Other infection experiments are reported with oat smuts (Ustilago avenæ and U. levis), 38 varieties belonging to 10 species of Avena being inoculated with spores of both smuts. Most of the hosts became infected, the percentage of infection varying from less than 2 to more than 88. A. barbata, A. brevis, and A. strigosa remained entirely free from the smuts. Of the common varieties of oats, a few, notably Burt and Early Ripe, remained practically free from infection.

Ecological observations on Ustilago zeæ, A. A. POTTER and L. E. MELCHERS (Abs. in Phytopathology, 7 (1917), No. 1, pp. 73, 74).—It having been reported that the nodal buds of maize were particularly subject to smut, the authors made an investigation of the matter. They report that conidia probably do not infect the corn plant directly, but that the result is rather the development of a virulent culture of the fungus in the leaf axil. A plant thus infected may become a center for aerial distribution, or, when rain occurs, the conidia may be washed down or splashed on other leaves.

The formalin treatment for controlling oat smut, J. A. Krall (*Proc. Iowa Acad. Sci., 28 (1916), pp. 593-620).*—Describing the loss annually caused by oat smut in Iowa and reviewing briefly the history and literature of oat-smut control measures, the author reports on his own experiments with treatments. Various fungicidal preparations were employed unsuccessfully as contrasted with formalin, 1 pt. of which to 20 gal, of water controlled the smut without materially decreasing the vitality of the seed. A bibliography is appended.

Some new facts concerning wheat smut, F. D. Heald (Proc. Wash. State Grain Growers, Shippers and Millers Assoc., 10 (1916), pp. 38-45, figs. 2).—Stinking smut, one of three types of smut that attack wheat, is the only one now serious in Washington. Recent studies have been noted in part (E. S. R., 34, p. 644). Two new features which stand out with special prominence are the occurrence of partially smutted grains and a general and extensive wind dissemination of the spores. These are discussed in connection with some of the better-known facts.

All or part of the heads of a stool may be smutted, and in a given head the smutting may be total or partial, showing wide variation. There is also great variation in the position and size of the smut mass in partially smutted grains. These grains in seed wheat would rarely be removed in cleaning, nor would the spores be killed by ordinary fungicidal treatment, and it is thought that a certain number will grow, vitiating the results from seed treatment. Fields may become infected by wind-blown spores. The spores of unbroken smut balls are not reached by fungicides, and will retain vitality in the soil for a year or more, though after liberation few remain alive for more than three months in moist soil and none of these are able to survive the winter. The records of spore traps show that during the thrashing period and the few weeks that follow there are probably many smut showers, the summer-fallowed fields becoming thickly strewn with spores borne by the wind.

The prevention of wheat smut, H. M. Woolman (*Proc. Wash. State Grain Growers, Shippers, and Millers Assoc., 10* (1916), pp. 45-49).—In continuation of the above discussion, the author states that although it is practically impossible by any one process to clean a very smutty lot of seed perfectly, the

wind or fanning-mill process, together with the open tank employing copper sulphate and salt or formaldehyde, will probably prove to be the best available means of control through seed treatment. However, this is admittedly inadequate to guard against the presence of partially smutted kernels.

Crop rotation is the best remedy for smut left in the field from former wheat crops, the rotation of oats, barley, or spring wheat with summer fallow being considered as fairly safe. Continuous alteration of wheat and summer fallow should be avoided. Deep plowing seems to help also, as will any operation on the stubble tending to crush the smut balls. Burning is advised in case of heavy stubble. Wind dissemination may occasionally be the sole cause of a smutty crop. Details of experiments regarding the viability of spores in the soil under varying conditions are considered to indicate that very early or very late sowing and replowing the summer fallow have considerable advantages. Another method suggested is tillage of the fallow after rains. Seed should be planted when the temperature is high.

Puccinia graminis on wheat kernels and its relation to subsequent infection, C. W. Hungerford (Abs. in Phytopathology, 7 (1917), No. 1, p. 73).—The author briefly reports experiments carried on at Madison, Wis., to determine whether P. graminis is able to infect wheat through the seed. Although the work has not been fully completed, the results so far obtained are considered to show that seed wheat infected with P. graminis does not cause infection of the wheat plant. Similar experiments have been started in cooperation with the Oregon Experiment Station with wheat infected with P. glumarum.

The Pseudopeziza leaf-spot diseases of alfalfa and red clover, F. R. Jones (Abs. in Phytopathology, 7 (1917), No. 1, p. 70).—Studies have been made of the Pseudopeziza leaf spots of alfalfa and red clover to determine possible relationships of the parasites as well as other facts regarding their life history.

The author reports having found that both fungi may be obtained in pure culture, slight morphological and distinct physiological differences having been observed. Only ascospores have been found to be produced in nature, while conidialike structures occurred in cultures. The germinating ascospores are said to penetrate the epidermal cells directly, the mycelium developing within the host cells and penetrating the cell walls. The fungus is considered to overwinter on dead leaves which escape decay, and ascospores developed either in old or new apothecia are a source of spring infection.

Experiments in the disinfection of alfalfa seed have shown that this treatment can not be depended upon for the prevention of leaf spot.

Bean mosaic, V. B. Stewart and D. Reddick (Abs. in Phytopathology, 7 (1917), No. 1, p. 61).—The authors report the extensive occurrence in New York in 1916 of a mosaic disease of beans, in some instances practically every plant being affected and the plants rarely setting pods. The disease was most frequently observed on pea beans, but other varieties of both dry and snap beans showed some infection. Evidence has been obtained which indicates that the disease is seed borne and may be readily transferred by inoculation.

Lima bean mosiac, J. A. McCLINTOCK (Abs. in Phytopathology, 7 (1917), No. 1, pp. 60, 61).—The author reports having observed over 25 per cent of several hundred plants of certain varieties of lima beans which were stunted and bore the dwarfed, mottled, wavy leaves characteristic of mosaic. The disease is serious, because the yield on infected plants is greatly decreased and the pods are smaller and malformed.

The celery-rot bacillus, H. Wormald (Jour. Agr. Sci. [England], 8 (1917), No. 2, pp. 216-245, pls. 2).—The author, in pursuance of an account previously given of a celery rot (E. S. R., 34, p. 244), states that the cause of this rot

is a bacillus which is described as differing only in minor respects from *Bacillus carotovorus*. Other common vegetables are also susceptible to attack by the organism, which is itself very sensitive to antiseptic and germicidal reagents, also to desiccation.

The development of the excial stage of Nigredo on red clover, I. E. Melhus and W. Diehl (Abs. in Phytopathology, 7 (1917), No. 1, p. 70).—Experiments have shown that the uredospore stage of N. fallens developed readily on red clover grown in greenhouses when the plants were about 6 in. tall. Subsequently, excia were observed, and during a period of about two weeks the excial stage became abundant and continued to develop for about a month when the temperature of the house was raised by increased sunshine.

White clover, alsike, and crimson clover in close proximity to the infected red-clover plants remained free from infection. Repeated attempts to transfer the rust to these hosts were without result, and it is believed that *N. fallens* is autocious and not heterocious as heretofore reported.

The excial stage of the red-clover rust, W. H. Davis and A. G. Johnson (Abs. in Phytopathology, 7 (1917), No. 1, p. 75).—The observations and experiments of the authors are considered to have shown that the red-clover rust (Uromyces fallens) is a long-cycled, autocious species, with pycnia, secia, uredinia, and telia on the same host.

Two transmissible mosaic diseases of cucumbers, I. C. Jagger (Abs. in Phytopathology, 7 (1917), No. 1, p. 61).—The author states that in addition to the mosaic disease known as white pickle, which has been previously described (E. S. R., 36, p. 350), a second distinct mosaic disease was observed in the vicinity of Rochester, N. Y. This disease is characterized by a mottling of the leaves, but shows no effect on the fruit. It has been repeatedly transmitted to healthy plants by rubbing them with crushed diseased leaves, and has also been transmitted to muskmelons and to summer crookneck squashes.

A Gnomonia on eggplant, C. W. Edgerton (Abs. in Phytopathology, 7 (1917), No. 1, p. 78).—The author reports having observed a species of Gnomonia on old eggplant stems during the winter season at Baton Rouge, La. The fungus has been repeatedly cultured and found similar to, if not identical with, the fungus causing eggplant blight (Phyllosticta hortorum). Inoculation experiments, however, have always given negative results. While it is possible that there may be no connection between the two, it is very probable that they are closely related species.

A malnutrition disease of the Irish potato and its control, H. A. Edson and O. Schreiner (Abs. in Phytopathology, 7 (1917), No. 1, pp. 70, 71).—The authors report the occurrence, in potato fields from Maine to Virginia during the summer of 1916, of a disease of potatoes characterized by a downward curling of the leaf margins accompanied by a bronzing and later a browning but not a yellowing of the foliage. Death of the leaves and sudden collapse of the stems at the ground level followed. Fungi appeared at and above the point of collapse, but investigations indicate that they are only weak parasites acting as contributing factors and that the primary cause of the trouble is malnutrition resulting from insufficient potash or perhaps an excess of nitrates in the presence of a minimum potash supply. In Maine the disease appears to be correlated with certain soil types and certain varieties, though not entirely so. The use of stable manure was found to be an excellent corrective.

The economic importance of mosaic of potato, P. A. MURPHY (Abs. in Phytopathology, 7 (1917), No. 1, pp. 72, 78).—As a result of his investigations, the author concludes that in an average crop of 300 bu. per acre there is a loss of 14 bu. per acre for every 1 per cent of mosaic present. The eating qualities of potatoes produced by mosaic plants are said to be unimpaired.

Strains of Rhizoctonia, J. ROSENBAUM and M. SHAPAVALOV (Abs. in Phytopathology, 7 (1917), No. 1, pp. 74, 75).—The authors report having isolated from potato stems a strain of Rhizoctonia which had produced a girdling and hollowing of the stems at or near the surface of the ground. Inoculation and culture experiments with this organism revealed certain characteristics, and it is considered possible that different strains of Rhizoctonia may offer an explanation for the conflicting reports regarding artificial infection.

Will Spongospora subterranea prove serious in Virginia? J. A. McClintock (Abs. in Phytopathology, 7 (1917), No. 1, p. 72).—As a result of planting in Virginia potatoes affected with powdery scab, the author concludes that powdery scab will not be prevalent either on the spring or on the fall planted potatoes even though the seed tubers are infected with the organism.

Host plants of Synchytrium endobioticum, A. D. COTTON (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 10 (1916), pp. 272-275).—It is said to have been proved beyond doubt that certain potato varieties are absolutely immune to the wart disease organism, S. endobioticum. No varieties which appeared resistant after thorough tests have broken down in this respect.

Other plant hosts, however, have been discovered. A few minute sporangia of the wart disease have been known to form on Solanum dulcamara and on S. nigrum. It is thought that the latter constitutes a greater danger than the former. It is considered as possible that the organism may have spread from wild Solanums to potato in Hungary, where the disease is said to have been first described.

Bordeaux spray for tip burn and early blight of potatoes, A. T. Erwin (Iowa Sta. Bul. 171 (1917), pp. 62-75, pls. 2, figs. 6).—Results are given of five years' experiments with tip burn and early blight of potatoes to determine whether, under corn-belt conditions, these diseases can be dealt with profitably by spraying with Bordeaux mixture.

The author has found that three applications of Bordeaux mixture gave an average annual increase of 10 bu. per acre, five applications 20 bu. per acre, and seven applications 22 bu. per acre. Basing his conclusions on these results, he recommends five sprayings with Bordeaux mixture, the first early in July, the applications to be repeated at approximately 10-day intervals.

A discussion is given of early blight and tip burn, their causes, temperature relations, etc.

Seed potato certification in Nova Scotia, P. A. MURPHY (Abs. in Phytopathology, 7 (1917), No. 1, p. 72).—A brief account is given of the method adopted in Nova Scotia for producing seed potatoes for the Bermuda seed trade.

Root disease of sugar cane, J. R. Johnson (Hacienda, 12 (1917), Nos. 4, pp. 117, 118, figs. 2; 5, pp. 146, 147, fig. 1).—This is a discussion of the destructive root disease of sugar cane, supposed to be caused primarily by Marasmius sacchari (though other fungi may be present), with suggestions for lessening injury therefrom, including such measures as insect control, soil selection and management, drainage, rotation, and resistance.

Tobacco diseases and their control, J. R. Johnson (Hacienda, 11 (1916), No. 12, pp. 372-374, figs. 3; 12 (1916), Nos. 1, pp. 26-28, figs. 3; 2, pp. 63, 64, figs. 3; 3, pp. 91-93, figs. 2; 12 (1917), No. 4, pp. 124-126, figs. 2).—Descriptions are given of several diseases, rots, or other sources of loss affecting the tobacco plant during its life or preparation for storage or market.

A Colletotrichum leaf spot of turnips, B. B. Higgins (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 4, pp. 157-162, pls. 2).—The attention of the author, at the Georgia Experiment Station, was called in 1914 to a leaf-spot disease of young turnip plants near Macon, Ga. The spots are said to be  $\frac{1}{4}$  in. or less in diameter, circular in outline, and of a pale green or straw color. The

disease also attacks the stems and seed pods, but experiments indicate that the fungus is not carried over in the living seed.

The organism causing the disease has been isolated and inoculation experiments have proved its pathogenicity. The organism is described by P. A. Saccardo as C. higginscanum n. sp. The author believes that the disease occurs in various portions of Georgia.

Temperature relations of apple rot fungi, C. Brooks and J. S. Cooley (Abs. in Phytopathology, 7 (1917), No. 1, p. 76).—It is stated that most apple rot fungi will grow at a lower temperature on corn-meal agar than on fruit and at a lower temperature on ripe fruit than on green fruit. With several, if not all, of the storage-rot fungi the initial stages of rotting are found to be more inhibited at low temperatures than is the germination of the spores. Various rots may finally make a fairly rapid development at temperatures at which the fungus is at first barely able to make a start. Even at favorable temperatures most of the fungi pass through a period of incubation on apples that is not evident on culture media.

Black root rot of the apple, F. D. Fromme and H. E. Thomas (U. S. Dept. Agr., Jour. Agr. Research. 10 (1917), No. 4, pp. 163-174, pls. 3, fig. 1; abs. in Phytopathology, 7 (1917), No. 1, p. 77).—The authors give a detailed account, in continuation of a previous note (E. S. R., 36, p. 649), of their investigation at the Virginia Experiment Station on the black root rot of the apple, which is said to be an infectious disease of considerable economic importance in the orchard sections of Virginia.

No prominent leaf characters have been observed for the disease, but the black encrustations on the surface of affected roots and the accompanying dark zonations in the bark and wood are considered reliable diagnostic characters. Field observations show that the root rot is infectious but that its progress is comparatively slow. Apple trees planted on newly cleared land are said to be more liable to attack than those on land cleared and cultivated for some time prior to planting.

Three species of Xylaria have been obtained in pure cultures from the apple roots, X. hypoxylon, which proved to be an active wound parasite, X. polymorpha, which seems to be only slightly pathogenic, and an undetermined species. X. hypoxylon is considered the chief cause of the root rot in Virginia.

Exclusion of the fungus, proper attention to cultivation, and elimination of contact with stumps of forest land are recommended as control measures.

Treatment of apple canker diseases, J. C. Whitten (Missouri Sta. Bul. 147 (1917), pp. 43, 44).—In a previous publication (E. S. R., 35, p. 848), the author reported the checking of about 90 per cent of apple tree cankers by the use of copper sulphate or corrosive sublimate. Observations have been continued during the past year to determine whether the cankers would break out again, but no further progress has been noticed in wounds which were apparently healed during 1913 and 1914.

In connection with this treatment, the author reports that mixing corrosive sublimate with paint has proved as effective in controlling canker as treating the scraped parts with the disinfectant and later painting for protection. In this treatment, the corrosive sublimate is dissolved in turpentine and mixed in proper proportion into the paint.

Jonathan spot, C. Brooks and J. S. Cooley (Abs. in Phytopathology, 7 (1917), No. 1, p. 76).—The authors claim that Jonathan spot increases up to a temperature of 20° C. (68° F.), but it is entirely inhibited at 30°. The disease, it is said, can be readily produced in saturated air in closed moist chambers, but seldom develops in a stirred air of 70 to 95 per cent relative humidity.

Control of apple scab by bleaching powder, W. S. BROCK and W. A. RUTH (Abs. in Phytopathology, 7 (1917), No. 1, p. 76).—The authors claim that the application of bleaching powder (calcium hypochlorite) to apple trees in 1916 reduced apple scab from 50 to 11.2 per cent without any injury to fruit or foliage.

Observations on pear blight in Illinois, F. L. Stevens, W. A. Ruth, G. L. Peltier, and J. R. Malloch (Abs. in Phytopathology, 7 (1917), No. 1, p. 75).— Experiments made by applying Bacillus amylovorus in suspension in water to pear buds in 1915 are believed to have indicated in 1916 that the bacilli did not hibernate in the buds. Infection of the spurs from hold-over trunk cankers was observed in 1916, but the organism appeared to be dead in all twig cankers. Leaves are said to be at no time naturally infected from the exterior, and on June 1 blades and pedicles could not be inoculated through the fruit while pedicles were still susceptible. The application of Bordeaux mixture is said to have controlled the floral infection without reducing the set of fruit.

Studies on peach yellows and little peach, M. A. Blake, M. T. Cook, and C. A. Schwarze (Abs. in Phytopathology, 7 (1917), No. 1, pp. 76, 77).—The results of investigations on these diseases are briefly described, and it is claimed that pits from diseased trees failed to germinate. Budding experiments with diseased buds indicate that the appearance of the disease in young trees varies with the source of bud wood.

Second progress report on investigations of leaf spot of cherries and plums in Wisconsin, G. W. Keitt (Abs. in Phytopathology, 7 (1917), No. 1, pp. 75, 76).—In continuation of investigations on the leaf spot due to Coccomyces hiemalis (E. S. R., 36, p. 149), the author reports having found that the trouble is satisfactorily controlled by the use of Bordeaux mixture of various strengths and lime-sulphur. Atomic sulphur, barium-sulphur, and self-boiled lime-sulphur in parallel applications did not control the disease satisfactorily.

A new disease of cacao, M. Turconi (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 26 (1917), I, No. 1, pp. 75-78).—In a preliminary note the author records the occurrence on Theobroma cacao, in the botanical garden at Pavia, of a leaf spot fungus described as a new species under the name Physalospora theobroma, and of two associated fungi also described as new, which are given the respective names, Stachylidium theobroma and Helminthosporium theobroma.

Diseases of chayote, R. Ramírez (Bol. Dir. Agr. [Mex.], 2 (1916), No. 2, p. 58, pl. 1).—The chayote is subject to injury by Cuscuta, Helix humboldtiana, and a disease affecting leaves and fruits associated with a Sphærella presumably as a primary agent and with several fungi named as secondary.

Mango disease in Yucatan, R. Ramírez (Bol. Dir. Agr. [Mex.], 2 (1916), No. 2, pp. 59, 60, pls. 2).—A disease attacking branchlets, flowers, and fruits of mango, also other plants, is described as due to Glæosporium mangiferæ.

Additional suggestions on treatment of hazel blight, M. B. WAITE (Amer. Nut Jour., 3 (1915), No. 6, p. 97).—The same treatment is recommended for hazel blight that has been found successful with black knot of plum and cherry, which yields to cutting out the blighted portions in February or early March before the spores have matured, and applying a dormant spray of Bordeaux mixture. Eradication of wild hazel is also considered important.

Winterkilling, sun scald, or sour sap of pecans, S. M. McMurran (Amer. Nut Jour., 3 (1915), No. 5, p. 82).—This is a descriptive account of the influence of cold weather succeeding warm days in November as causing injury or death to pecan trees which had renewed growth in the fall after a serious check due

to summer drought. Wrapping the trees with sacking for about 4 ft. above the ground practically prevented the trouble.

Notes on pecan diseases, S. M. McMurran (Amer. Nut Jour., 4 (1916), No. 6, pp. 81, 86, figs. 3).—In a block of pecan trees sprayed for scab with Bordeaux mixture five times about two weeks apart, from May 29 to August 8, 1914, the brown leaf spot disease (Cercospora fusca) was effectively controlled, while the unsprayed trees were almost defoliated by September. Nursery leaf blight (Phyllosticta caryæ) was controlled with from three to five sprayings. A defoliation of pecan occurring in southern Louisiana in late summer appeared to be associated with water supply. A dieback observed at a point in Louisiana and one in Georgia were apparently due to soil and seasonal conditions. Black pit, a nut disease said not to have been described previously, is thought to be nonparasitic in character.

Blight and melaxuma of walnut, C. W. Beers (Amer. Nut Jour., 4 (1916), No. 2, pp. 18, 19, 21, figs. 3).—Both blight and melaxuma of walnut are reported to have been brought under study and control.

An investigation of forest tree diseases, G. M. REED, LUCILE KEENE, JESSIE CLINE, and EMILY HARDESTY (Missouri Sta. Bul. 147 (1917), pp. 28, 29).—The authors report having collected a number of polyporous fungi on living trees during the year, among them Fomes fraxinophilus on ash, F. robiniæ on black locust, and F. everhartii on oak. Studies on fungi connected with the decay of fence posts are said to be in progress.

Boleti and mycorrhiza upon forest trees and an unusual mycorrhiza upon white oak, L. H. Pennington (Abs. in Phytopathology, 7 (1917), No. 1, p. 74).—Six species of Boletus are reported as connected with mycorrhiza of forest trees, usually oaks. A peculiar form of mycorrhiza found upon white-oak roots is briefly described. Attempts to inoculate the roots of other trees with this fungus have thus far failed.

Blight-resistant chestnuts from China, G. H. Corsan (Amer. Nut Jour., 2 (1915), No. 4, p. 54, figs. 2).—The author notes the observations made by Meyer in the course of studies carried out by him in northern China (E. S. R., 35, pp. 29, 140) regarding the high resistance of a Chinese chestnut (Castanea mollissima) to chestnut blight, the wounds caused by the attack on this species healing spontaneously.

Breeding chestnuts for disease control (Amer. Nut Jour.,  $\frac{1}{4}$  (1916), No.  $\frac{1}{4}$ , pp. 56, 57, figs.  $\frac{1}{4}$ ).—Brief mention is made of work in progress in the testing of hybrids between the American native chinquapin and Japanese chestnut. The  $F_1$  and  $F_2$  hybrids are highly resistant to the chestnut bark disease and show other desirable characters, as do also four generations of hybrids between Japanese and Chinese chestnuts.

Violent outbreak of Oïdium on oak in France, E. Noffean (Jour. Agr. Prat., n. ser., 29 (1916), No. 19, p. 326).—A brief description is given of the mode of attack by Oïdium on oak, which, it is said, has not ceased since the time of its introduction to cause damage and which is becoming serious in Sologne

Oïdium on oak, F. Convert (Jour. Agr. Prat., n. ser., 29 (1916), No. 20, pp. 343, 344).—The author, replying to the article noted above, states that an American oak which does well in France is resistant to Oïdium.

American oaks resistant to Oïdium in Sologne, E. Noffbay (Jour. Agr. Prat., n. ser., 30 (1917), No. 3, pp. 54, 55).—Following up the information noted above, the author made examination of a number of oaks of the American species Quercus palustris in Sologne, finding them practically free from attack by Oïdium.

A species of Chrysomyxa new to North America, H. S. Jackson (Abs. in Phytopathology, 7 (1917), No. 1, p. 78).—The author reports a short-cycled form referable to the genus Chrysomyxa occurring on leaves of Picea engelmannii.

Mycelium of the white pine blister rust, R. H. Colley (Abs. in Phytopathology, 7 (1917), No. 1, p. 77).—The author describes some of the morphological characters of the mycelium of Cronartium ribicola as it occurs on the white pine.

Pycnial scars, an important diagnostic character for the white pine blister rust, R. H. Colley (Abs. in Phytopathology, 7 (1917), No. 1, p. 77).—The occurrence of scars due to pycnia is said to offer a valuable diagnostic character for the identification of the white-pine blister rust.

"Black thread" disease of Hevea in Burma, J. F. Dastur (Dept. Agr. Burma Bul. 14 (1916), pp. 4, pl. 1).—A brief account is given of the development and spread of the black thread disease of Hevea in Burma due to Phytopthora sp. The fungus remains dormant in the tissues during the monsoon after tapping is stopped, and resumes activity when tapping is resumed. The principal measures recommended as preventive are thinning out thickly planted areas, removal of diseased fruits, and suspension of tapping on trees showing black thread.

Phytophthora sp. on Hevea brasiliensis, J. F. Dastur (Mem. Dept. Agr. India, Bot. Ser., 8 (1916), No. 5, pp. 217-232, figs. 10).—This is a more detailed account than that above noted of the Phytophthora disease of H. brasiliensis, which is thought to have been present in Burma since 1903, at least on Hevea fruits.

The effects of the fungus attack on the tapping areas and in the epidermal cells of the fruit are described, as are also studies in the morphology and biology of the fungus. These are claimed to show that there may be two stem diseases present in *H. brasiliensis* due to different species of Phytophthora, one of these being *P. faberi*. In those parts of Burma where the rainfall is not excessive, the author found that suspension of tapping during the rainy season checked the disease.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

New mammals from North and Middle America, E. A. Goldman (Proc. Biol. Soc. Wash., 30 (1917), pp. 107-116).—The San Miguel Island opossum (Didelphis marsupialis particeps) from San Miguel Island, Panama; savanna marmosa (Marmosa mexicana savannarum) from Panama; Bangs collared peccary (Pecari angulatus bangsi) from Panama; Pinacate desert mouse (Peromyscus eremicus papagensis) from Sonora, Mex.; Nevada bushy tailed wood rat (Neotoma cinerea lucida) from Nevada; Wyoming kangaroo rat (Perodipus ordii luteolus) from Wyoming; black naped agouti (Dasyprocta punctata nuchalis) from Panama; Richmond's agouti (D. punctata richmondi) from Nicaragua; Nelson's false vampire (Vampyrus spectrum nelsoni) from Vera Cruz, Mex.; and the northern yellow-shouldered bat (Sturnira lilium parvidens) from Papayo, Guerrero, Mexico, are described as new.

The conservation of our northern mammals, C. G. Hewitt (Com. Conserv. Canada Rpt., 7 (1916), pp. 32-40, pls. 2).—This paper deals particularly with the caribou, musk ox, etc., and means for their protection. Colored maps show the approximate distribution of the barren ground caribou (Rangifer arcticus) and musk ox (Ovibos moschatus) and related forms in Canada.

Control of the pocket gopher in California (California Sta. Bul. 281 (1917), pp. 15, figs. 4).—The first of the two parts of this bulletin (pp. 3-13), by J. Dixon, deals with the natural history of the pocket gopher and various

methods of control; the second part (pp. 14, 15), by E. R. de Ong, with a method of poisoning pocket gophers, which consists in the use of sweet potatoes, parsnips, or carrots, 8 qt.; flour paste, 0.5 pint; strychnin alkaloid, powdered, 0.25 oz.; and saccharin, 0.0625 oz.

Varying hares of the prairie Provinces, N. CRIDDLE (Agr. Gaz. Canada, 4 (1917), No. 4, pp. 260-263).—Lepus americanus and its various geographic races, with a range in western Canada almost as extensive as the woodlands, is a source of great injury to young trees through gnawing and eating the bark. The destruction of acres of aspen poplars in this way after a severe winter is said to be not an uncommon sight. Larches are also denuded of their bark, while spruce and pine are generally stripped of their branches. The greatest injury thus far recorded is said to have occurred during the winter of 1915-16. Enormous numbers of aspen poplars were destroyed in southern Manitoba and Saskatchewan and the infestation appears to have extended far northward. Practically all kinds of trees and shrubs were attacked, plum, cherry, and apple trees frequently being cut to the ground and in some instances quite old orchards were badly injured.

Their natural enemies are briefly considered, as are methods of protection by means of poultry netting, poisoning, and shooting.

On the ecology of the vegetation of Breckland, E. P. Farrow (Jour. Ecology, 5 (1917), No. 1, pp. 1-18, pls. 6, fig. 1).—This deals with the general effects of rabbits on the vegetation.

Description of a new race of Say's ground squirrel from Wyoming, A. H. Howell (Proc. Biol. Soc. Wash., 30 (1917), pp. 105, 106).—Callospermophilus lateralis caryi n. subsp. is described from Wyoming.

Two new pocket mice from Wyoming, E. A. Goldman (Proc. Biol. Soc. Wash., 30 (1917), pp. 147, 148).

Mutanda ornithologica, I, II, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 30 (1917), pp. 75, 76, 125, 126).

The birds of South America, Lord Brabourne and C. Chubb (London: R. H. Porter, 1912, vol. 1, pp. XIX+504, pl. 1).—This first volume, which consists of a list of South American birds, terminates a proposed 16-volume work, owing to the death of Lord Brabourne at the front in 1915. It contains a systematic index, a classified and systematic list of 4,561 forms representing 874 genera, and an alphabetical index.

Illustrations to the birds of South America, H. Grönvold (London: John Wheldon & Co., vol. 2, 1915, pt. 1, pls. 19; 1916, pts. 2, pls. 4; 3, pls. 4; 4, pls. 4; 5, pls. 4; 1917, pt. 6, pp. 11, pls. 3).—These six parts consist of colored plutes of the game birds and waterfowl of South America, originally intended to form part of 400 hand colored plates illustrating the above-mentioned work. Short descriptive notes by H. K. Swann on most of the species illustrated preface the same.

A new honey eater from the Marianne Islands, A. WETMORK (Proc. Biol. Soc. Wash., 30 (1917), pp. 117, 118).—Myzomela rubratra saffordi n. subsp. is described from the islands of Guam and Saipan.

A new shrew from Nova Scotia, H. H. T. JACKSON (Proc. Biol. Soc. Wash., 30 (1917), pp. 149, 150).—A new shrew is described under the name Sorex fumeus umbrosus.

Description of a new genus of Anatidæ, H. C. OBERHOLSEE (Proc. Biol. Soc. Wash., 30 (1917), pp. 119, 120).—The genus Horizonetta is erected for the Laysan teal (Anas laysanensis).

Notes on rearing insects for experimental purposes and life history work. A. M. Wilcox (Psyche, 24 (1917), No. 1, pp. 7-12, pls. 2).

The growth of insect blood cells in vitro, R. W. Glaser (Psyche, 24 (1917), No. 1, pp. 1-7, pl. 1).—This is a report of observations on the morphology and behavior of growing insect blood cells, made during the course of a study of the pathological changes which take place in insect tissue, in which the tissue was cultivated in vitro.

Toxic values and killing efficiency of the arsenates, A. L. Lovett and R. H. Robinson (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 4, pp. 199-207).—This is a report of work carried on at the Oregon Experiment Station in continuation of that of Tartar and Wilson previously noted (E. S. R., 34, p. 548). The results afford further verification of the earlier work and give material data on (1) the comparative time and (2) the approximate amount of lead hydrogen arsenate and basic lead arsenate required to kill small caterpillars and nearly mature caterpillars; and (3) the proportion of these arsenates devoured by the small and mature caterpillars that passes through the alimentary canal of the larvæ. The work has been summarized by the author as follows:

"Lead hydrogen arsenate has a higher killing efficiency at a given dilution than either calcium or basic lead arsenate. It requires a longer period of time to kill the nearly mature caterpillars than the small forms. All of the arsenic devoured by the insects in feeding upon sprayed foliage is not assimilated, but a portion passes through the intestinal tract in the excrement. The percentage amount of the arsenic assimilated depends upon the arsenate used; lead hydrogen arsenate was assimilated readily and most of the arsenic was retained in the tissue, while much of the basic lead arsenate was found in the excrement. It requires approximately 0.1595 mg. of arsenic pentoxid to kill 1,000 small tent caterpillars and approximately 1.84 mg. of arsenic pentoxid to kill 1,000 nearly mature tent caterpillars, irrespective of the particular arsenate used as a spray.

"Preliminary experiments on the burning effects of calcium arsenate indicate too severe injury to warrant the practical use of this spray."

Winter cover washes, A. H. Lees (Ann. Appl. Biol., 2 (1916), No. 4, pp. 245-250).—In continuation of work previously noted (E. S. R., 34, p. 253), it was found that the best cover wash consists of lime 30 lbs., glue 2 lbs., potassium dichromate § ez., and water 10 gal. "This lime-glue-dichromate mixture has been tried against ordinary lime wash at Long Ashton and has given decidedly superior results. An application to an apple tree stopped aphis hatching to such an extent that hardly an aphis was to be seen on it throughout the season though control trees were very badly attacked. The tree stood out all the season from its fellows by the healthy green uncurled leaves and at the end of the season by its very numerous well-developed fruit buds."

Accessory wetting substances with special reference to paraffin emulsions, A. H. Lees (Ann. Appl. Biol., 3 (1917), No. 4, pp. 141-149, fig. 1).—This discussion is accompanied by a table which gives the results of tests of the wetting power of paraffin emulsions and of other auxiliary wetting agents on certain natural surfaces.

The author concludes that there is no object in introducing greater quantities of paraffin or soap since a 2 per cent soap-paraffin emulsion (20 lbs. soap and 2 gal. of paraffin to 100 gal. water) gives perfect wetting. The work has shown that it is not possible to reduce the quantity of either the paraffin or soap without destroying the desirable qualities of the mixture, and that the above mentioned mixture is the cheapest that can be used which at the same time has the highest wetting power.

"The value of this 2 per cent emulsion lies not so much in its own killing power as in the fact that it can act as a carrier, so to speak, for other fungicidal or insecticidal bodies which, used alone, would prove themselves insufficient to

kill. Thus, liver of sulphur, used alone, has no great controlling effect on American gooseberry mildew but, combined with paraffin emulsion, has given promising results in a commercial scale experiment undertaken by Barker and myself. In the direction of insect control it also shows promise. While dilute solutions of nicotin are without decided action on adult caterpillars or difficultly killed beetles, such as *Byturus tomentosus*, the raspberry beetle, it has been found possible, at any rate on the small scale, to kill these by uniting the same nicotin solution with 2 per cent paraffin emulsion."

[Progress report of investigational work in entomology] (Missouri Sta. Bul. 147 (1917), pp. 32-34).—In dusting and spraying experiments on field corn for the control of the corn ear worm, by L. Haseman, six different treatments were applied on an area of 2 acres on creek bottom land, but the worms were so scarce that the results did not justify the expense of application. One plat dusted with 3 parts of arsenate of lead powder and 1 part of powdered sulphur showed a reduction in the infestation of 50 per cent, while another plat sprayed with a solution containing 1 tablespoonful of arsenate of lead powder to 1 gal. of water showed a reduction of 75 per cent, but on a plat of upland corn numerous treatments did not appear to check the pest in any degree.

Other work briefly reported upon includes investigations of the Hessian fly-resistant qualities of different varieties of wheat, by L. Haseman and C. G. Vinson, an account of which by Haseman has been previously noted (E. S. R., 35, p. 759); of insect pests of melon and related crops, by L. Haseman; of insects injurious to nursery stock, by L. Haseman, K. C. Sullivan, and A. H. Hollinger; and of the scale insects of Missouri, by A. H. Hollinger.

Report of the State entomologist on injurious insects and fungi of trees in 1914, T. H. Schöyen (Indber. Norske Skogv., 1914, pp. 150-155, pl. 1).—This report on the occurrence of important insect enemies and fungus diseases includes an account of the damage caused to trees by mice.

Preliminary account of entomological work in 1914, B. N. Zolotarevskii (Predvaritel'nyi Otchet o Rabotakh po Entomologii v 1914. Stavropol: Selsk. Khoz. Opytn. Sta., 1915, pp. 12).—This report deals with the occurrence of the more important insects of the year, particularly those attacking cereal crops.

Some East African insects of economic importance, R. H. DEAKIN (Ann. Appl. Biol., 2 (1916). No. 4, pp. 241-244).—Brief notes based upon observations during a period of 18 months.

Insect enemies of man and the household and the diseases they convey, A. Berlese (Insetti delle Case e dell' Uomo e Malattie che Diffondono. Milan: Ulrico Hoepli, 1917, pp. XII+293, figs. 100).—A small handbook.

Household and camp insects, E. P. Felt (N. Y. State Mus. Bul. 194 (1917), pp. 84, figs. 41).—This is a summary of information on insects of the household and camp, particular attention being given to control measures.

Studies on Coccobacillus acridiorum and on certain intestinal organisms of locusts, E. M. DUPORTE and J. VANDERLECK (Ann. Ent. Soc. Amer., 10 (1917), No. 1, pp. 47-62).—Part 1 of this report of studies, made at McGill University, consists of experiments on the control of locusts by the use of C. acridiorum, and part 2 of descriptive studies on C. acridiorum and 16 related native organisms. The results indicate that the biological method for the control of the locust can not take the place of the measures now in use under the conditions which obtain in eastern Canada.

The pathogenicity of *C. acridiorum* was tested for all species of locusts and grasshoppers, seven in number, commonly occurring in large numbers in the region. *Gryllus pennsylvanicus*, one of the common field crickets, was also found to be susceptible to the disease. The yellow bear caterpillar [(*Spilosoma*) *Diacrisia virginica*] and the Colorado potato beetle, larvæ and adults,

were also tested, and all individuals of the former were dead in less than 48 hours, but the latter was not susceptible to the disease.

The azalea lace bug, Stephanitis pyrioides, E. L. DICKERSON and H. B. Weiss (Ent. News, 28 (1917), No. 3, pp. 101-105, pl. 1).—A report of studies of the morphology and biology of this tingitid which has recently become abundant and widespread enough in New Jersey to do considerable damage to azaleas.

This species, which was originally described by Scott from Japan in 1874, is said to have been introduced into New Jersey in the egg stage on evergreen azaleas from that country. It is also known to occur at Bala, Pa., and Washington, D. C., and in Holland. The nymphs and adults feed on the undersurface of the leaves, abstracting the sap and causing a discoloration of the foliage on the upper surface. In severe infestations the leaves become almost white, many of them drying completely and dropping off. The underside of the leaves is disfigured by the insect's excrement.

In central and southern New Jersey, the egg. in which stage the winter is passed, hatches the latter part of May. The length of each of the five nymphal stages varies from three to six days. The appearance of the adults the latter part of June is closely followed by oviposition which lasts for a period of two weeks. These eggs require on an average two weeks for hatching. Growth is completed by the last week in July and the first week in August and many new adults are present. During the first two weeks of August eggs are again laid and by the middle of and last week in September many adults of this brood are present, the overwintering eggs being deposited at this time and during the first part of October. Thus there are three broods in southern New Jersey, the average length of each being about one month. In the central and northern parts of the State, however, there are only two and a partial third.

The lace bug on azaleas may be controlled by spraying with whale-oil soap at the rate of 5 or 6 lbs. to 50 gal. of water, preferably shortly after the overwintering eggs have hatched.

The Cicadellidæ of Wisconsin, with description of new species, J. G. Sanders and D. M. DeLong (Ann. Ent. Soc. Amer., 10 (1917), No. 1, pp. 79-97, figs. 49).—The authors list 206 species and varieties representing 38 genera, of which 13 species are described as new.

Spraying for apple sucker (Psylla mali), F. R. Petherbridge (Ann. Appl. Biol., 2 (1916), No. 4, pp. 230-234).—"These experiments indicate that lime and salt [lime 150 lbs., salt 30 lbs., and water 100 gal.] may be effective in preventing a large proportion of apple sucker eggs from hatching. Lime wash was also fairly effective. Soft soap and nicotin, or treacle and nicotin, were the most effective after the suckers had hatched. Spraying to prevent the eggs from hatching is not sufficient to keep this pest under control, but should be followed by an application of nicotin and soft soap, or treacle and nicotin, to kill those which have hatched."

Some observations on the egg of Psylla mali, A. H. Lees (Ann. Appl. Biol., 2 (1916), No. 4, pp. 251-257, figs. 9).—A brief report of a morphological and embryological study.

Plant lice on potatoes, W. R. Brown (Rural New Yorker, 76 (1917), No. 4446, p. 1053, flg. 1).—This records serious injury to the potato in Hampshire County, Mass., by the potato aphis during the summer of 1917.

An instance is cited of a promising 8-acre field which was killed by the plant lice before the tops were half grown. The first application of blackleaf 40 was inefficient due to too great a dilution. The second application killed the aphids, but the plants had been so weakened by the lice and the turning of the potato tops with a hand rake in order that the spray might hit the underside of the leaves that they died in a short time.

J. S. Regan, of the Massachusetts Agricultural College, who has conducted experiments, recommends the use of blackleaf 40, 1.25 teaspoonfuls, and 1 oz. of soap to a gallon of water, applied with an angle disk nozzle carried close to the ground so that it will direct the spray upwards and hit the underside of the leaves. Whale or fish-oil soap used at the rate of 1 lb. to 6 gal. of water is said to be nearly if not quite as good. Either of these insecticides properly applied was found to be from 98 to 99 per cent effective.

The louse and its relation to disease.—Its life history and habits and how to deal with it, B. F. Cummings (Brit. Museum (Nat. Hist.), Econ. Ser., No. 2 (1915), pp. 16, pl. 1, figs. 2).—This is a popular account.

The rate of increase of the pink bollworm in green bolls in the period July to November, 1916, L. H. Gough (Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 13 (1917), pp. 20, pl. 1).—The data here given are based upon 106,400 bolls examined.

While the highest percentage of bolls attacked was found the second week of October, the largest number of bolls attacked must have existed during the third week in September. "If the figures on which our calculations have been based are accepted as sufficiently accurate, it can be estimated that when at its maximum the Gelechia population reached at least 4,500 individuals per thousand cotton plants (500 holes). Supposing 26,000 plants to the feddan [1.04 acres], this gives the alarming total of about 120,000 worms to the feddan...

"Considering that Gelechia is an imported pest, which has been in Egypt less than ten years, its increase has been enormous. It now occurs, everywhere where cotton is grown in Egypt; in the last week of October, 87 per cent of the green bolls in Lower, 78 per cent in Middle, and 60 per cent in Upper Egypt were attacked by it; and we have received specimens of the adult from the desert at Romani."

On the rate of increase of Gelechia gossypiella larve in green bolls during 1916, L. [H.] Gough (Bul. Soc. Ent. Egypte, 9 (1916), No. 4, pp. 113-115).—Substantially noted above.

The pink bollworm, J. P. Buchanan (Cong. Rec., 55 (1917), No. 126, pp. 7140-7145).—An address in which attention is called to the danger of this important cotton pest becoming established in the United States.

What effect has flooding of a cotton field by infiltration from high Nile on the numbers of the pink bollworm in that field? (Bul. Soc. Ent. Egypte, 9 (1916), No. 4, pp. 105-108).—It is pointed out that since (Gelechia) Pectinophora gossypiella pupates to a very large extent on the ground amongst fallen leaves, etc., it is very probable that a heavy flooding lasting for weeks will cause the death of the pupe and pupating larvæ. Since Earias insulana larvæ pupate to a much greater extent on the plants they are much less likely to be destroyed by flooding.

Sciara tritici, a fly injurious to seedlings, F. W. Edwards and C. B. WILLIAMS (Ann. Appl. Biol., 2 (1916), No. 4, pp. 258-262).—This dipteran is reported to be the source of injury to Primula seedlings.

The mosquitoes of North and Central America and the West Indies, L. O. Howard, H. G. Dyar, and F. Knab (Carnegie Inst. Washington Pub. 159, vol. 4 (1917). pp. 525-1064).—This second part of the systematic description, the first part of which comprises volume 3 previously noted (E. S. R., 34, p. 453), completes the work. In these two volumes the authors recognize 380 species (besides two which are synonyms, as pointed out in the appendix) included in 25 genera occurring within the North American Continent from the southern edge of Canada to the Isthmus of Panama, including the Antilles and Trinidad. Adding to these the species previously mentioned as not included and the ones

described since the appearance of volume 3, there is a total of 398 described species from the region included in this work.

In the tribe Sabethini (pp. 19-187 of vol. 3) 8 genera and 85 species are recognized, including Sabethes, represented by 3 species; Sabethinus, 2 species; Sabethoides, 1 species; Limatus, 3 species; Wyeomyia, 65 species (4 new to science); Prosopolepis, 1 species; Lesticocampa, 5 species (2 new); and Joblotia, 3 species. In the tribe Culicini (pp. 189-523 of vol. 3 and pp. 525-1038 of vol. 4) 17 genera and 297 species are treated, including Dinomimetes, represented by 1 species; Deinocerites, 5 species; Dinanamesus, 1 species; Culex, 104 species (6 new); Carrollia, 2 species; Lutzia, 2 species (1 new); Culiseta, 6 species; Mansonia, 7 species; Psorophora, 29 species; Aedes, 83 species (5 new); Hæmagogus, 4 species; Orthopodomyia, 5 species; Aedeomyia, 1 species; Uranotænia, 11 species (1 new); Megarhinus, 11 species; Anopheles, 21 species (1 new); and Cœlodiazesis, 1 species.

Under each species are given the synonymy with references to the literature; copies of the original description and the original descriptions of the synonyms; detailed descriptions of the male, female, and larva, when known; distribution, including a full citation of localities, date, and collector; and what is known of the life history and habits.

It is pointed out that only a few parts of the region have been at all adequately explored, many large areas not at all, so that many more species doubtless wait discovery. A large proportion of the material studied consists of bred specimens with larvæ associated. Sixteen pages are devoted to the yellow-fever mosquito, for which the name Aedes calopus is used, though, as shown in a foot-note, the strict application of the rule of priority will necessitate the use of the name A. argenteus (Poiret).

Errors noted in the preceding volumes are corrected in an appendix (pp. 1039-1042) to which are added a few supplementary notes.

The relation between the hatching of the eggs and the development of the larvæ of Stegomyia fasciata (Aedes calopus) and the presence of bacteria and yeasts, E. E. Atkin and A. Bacot (Parasitology, 9 (1917), No. 4, pp. 482-536).—The authors find that the larvæ of S. fasciata greedily consume both bacteria and yeasts, on which they can thrive in the absence of any other food, whereas in very many instances they fail entirely to develop on a variety of nutritive fluids and particles, including dead bacteria, under sterile conditions. The rearing of adults under sterile conditions is so exceptional that they feel justified in concluding that the presence of bacteria or yeast is a practical necessity for the maintaining of the species.

On the biology and economic significance of Tipula paludosa, J. Rennie (Ann. Appl. Biol., 2 (1916), No. 4, pp. 235-240, pl. 1; 3 (1917), No. 2-3, pp. 116-137, pls. 3, figs. 3).—The first part of this paper consists of a preliminary report of observations; the second part deals with hatching, growth, and habits of the larva.

Notes on New England Tachinidæ, with the description of one new genus and two new species, H. E. SMITH (Psyche, 24 (1917), No. 2, pp. 54-58).—Pseudotachinomyia webberi n. g. and n. sp. and Sciasma frontalis n. sp. from Massachusetts are described.

The larvæ of *Pelatachina pellucida*, which emerged from the larvæ of *Euvanessa antiopa* during August, hibernated in the puparia. From 344 of the lepidopterous larvæ 214 puparia were obtained, but since superparasitism existed to a great extent in the host larvæ, the figures do not indicate the exact percentage of parasitism. This is thought to be the first record of a species of the genus having been reared in North America, although the rearing of the genotype, *P. tibiolis* from *Vanessa urticæ* in Europe has been recorded.

Compsilura concinnata, a European species introduced into and established in this country as one of the foremost primary parasites of the gipsy and brown-tail moths, is known to have been reared from more than 20 species of native North American Lepidoptera. It is said to be particularly prolific as a parasite of E. antiopa, in certain instances the percentage of parasitism of this host in the New England States being well over 50. The data at hand appear to establish the fact that it hibernates through the winter in New England in the pupa of E. antiopa.

The collection of Exoristoides slossonæ at Bennington, Vt., is recorded and Exorista spinipennis is said to be a synonym of E. slossonæ.

Seasonal abundance of flies in Montana, R. R. PARKER (Ent. News, 28 (1917), No. 6, pp. 278-282, pl. 1).—This is a report of the seasonal abundance of flies, especially the house fly, based upon work done at Laurel, Mont., during July and August, 1914.

Empusa muscæ versus Musca domestica, H. T. Güssow (Ann. Appl. Biol., 5 (1917), No. 4, pp. 150-158, pl. 1).—In discussing the subject the author reviews the work of Hesse, previously referred to (E. S. R., 34, p. 254), and records cultural experiments and other observations on E. muscæ.

Report on a trial of tarred felt disks for protecting cabbages and cauliflowers from attacks of the cabbage root fly, J. T. Wadsworth (Ann. Appl. Biol., 3 (1917), No. 2-3, pp. 82-92, pl. 1).—A detailed report of experiments with cabbage and cauliflower, conducted at Manchester University, which show tarred felt disks to be a very effective means of protection. A list of 15 references to literature on the subject is appended.

Two new cambium miners, C. T. GREENE (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 6, pp. 313-318, pl. 1).—The author describes two new species of Agromyza, the larvæ of which mine in the cambium of the living tree, causing a scar which is known as "pith-ray fleck." The mines somewhat resemble those of the cambium miner (Agromyza pruinosa) in river birch (Betula nigra), an account of which has previously been noted (E. S. R., 30, p. 855).

The species first described is Agromyza aceris, which mines down the cambium in the trunk and roots of the red maple (Acer rubrum), occurring quite commonly at Falls Church, Va., and French Creek, W. Va. The second species, described as A. amelanchieris, was taken from the trunk near the ground and from the roots of the service berry or shadbush (Amelanchier canadensis) at French Creek, W. Va.

Investigations of the Anthomyidæ, the larvæ of which are carnivorous, D. Keilin (Parasitology, 9 (1917), No. 3, pp. 325-450, pls. 11, flgs. 41).—The species considered include Melanochelia riparia, Graphomyia maculata, Allognota agromyzina, Phaonia spp., Myospila meditabunda, Mydæa spp., Hydrotæa spp., Muscina spp., etc.

New genera and species of American muscoid Diptera, C. H. T. Townsend (*Proc. Biol. Soc. Wash.*, 30 (1917), pp. 43-50).—Thirteen genera and four species are here described as new.

The viability of Melophagus ovinus, the sheep louse fly, sheep ked, or sheep "tick," Georgina Sweet and H. R. Seddon (Vet. Jour., 73 (1917), No. 502, pp. 6-14).—The authors' experiments show that the life of the sheep tick in shed wool is short under uniform temperature, whether cool or moderate. The state of nutrition does not seem to influence the viability of these ticks.

Fleas as a menace to man and domestic animals.—Their life history, habits, and control, J. WATERSTON (Brit. Muscum (Nat. Hist.), Econ. Ser., No. 3 (1916), pp. 21, pl. 1, figs. 6).—A popular account.

Observations on the larval and pupal stages of Agriotes obscurus, G. H. Ford (Ann. Appl. Biol., 3 (1917), No. 2-3, pp. 97-115, pls. 2, flg. 1).—This is a report of studies of the immature stages of the common wireworm in Cheshire, North Staffordshire, and South Lancashire.

The life of the larva has been found to be probably four rather than five years. "The larva pupates in an earthen cell in the ground, down to 1 ft. deep; the pupal period is about three weeks; the imago remains resting motionless in the pupal cell for roughly two months, after which it comes to the surface, and hibernates under stones, clods, etc., until the next season."

A bibliography of 20 titles is appended.

Note on attacks of Phyllotreta vittula on spring corn, F. R. Petherbeide (Ann. Appl. Biol., 3 (1917), No. 2-3, pp. 138, 139).—The author records the injury caused by this beetle to young barley plants at Warminster and Rothamsted, England.

A flea-beetle which attacks potato plantations on the plateaus, M. T. Dawe (Rev. Agr. [Colombia], 2 (1916), No. 8, pp. 458-461; abs. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 3, pp. 133, 134).—Epitrix nigrownea, which closely resembles E. cucumeris, is said to attack the young, tender leaves of potatoes as soon as they appear and sometimes ruins an entire plantation in Colombia.

The bark borer (Dendroctonus micans), I. Trägårdh (Skogsvårdsför. Tidskr., 14 (1916), No. 5, pp. 484-486, figs. 3).—This borer, the largest of the European species, destroys an enormous number of both pine and fir trees each year, particularly those which have attained a growth of 25 to 50 years. The paper includes notes on its life history and habits, but no mention is made of control measures.

On new neotropical Curculionidæ, G. A. K. Marshall (Ann. and Mag. Nat. Hist., 8. ser., 18 (1916), No. 108, pp. 449-469; abs. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 3, p. 124).—One genus, 17 species, and one subspecies, largely from the West Indies and South America, are described as new. The paper includes descriptions of one species and one subspecies of Diaprepes new to science and a review of the paper by Pierce on the genus Diaprepes previously noted (E. S. R., 33, p. 360).

The fauna of British India, including Ceylon and Burma.—Coleoptera. Rhynchophora: Curculionidæ, G. A. K. Marshall (London: Taylor & Francis, 1916, pt. 1, pp. XV+367, figs. 108; rev. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 3, p. 123).—This volume contains an introductory account of the Curculionidæ in its wide sense, Lacordaire's system of classification being adopted. Two subfamilies, the Brachyderinæ and Otiorrhynchinæ, comprising 342 species, are dealt with in detail. Fifteen genera are erected and 179 species are described as new.

The fauna of British India, including Ceylon and Burma.—Hymenoptera: Ichneumonidæ, I, C. Morley (London: Taylor & Francis, 1913, vol. 3, pp. XXXVI+531, pl. 1, figs. 152).—This first part of volume 3 of the work previously noted (E. S. R., 15, p. 280), dealing with the subfamily Ichneumones deltoidei, first gives a bibliography of the literature consulted. This is followed by a summary of the known Indian forms, consisting of 406 species representing 140 genera; an index to the Indian hosts; a glossary of terms employed in the work; and a systematic index. In the introduction to the main part which follows, the author discusses the history of the group, metamorphoses, internal and external structure, and classification.

Twelve genera, 99 species, and 3 varieties are described as new.

Guide to the insects of Connecticut.—III, The Hymenoptera, or wasp-like insects of Connecticut, H. L. VIERECK ET AL. (Conn. State Geol. and Nat. Hist. Survey Bul. 22 (1916), pp. 824, pls. 10, figs. 15).—This third part of the work

previously noted (E. S. R., 26, p. 147) deals with the Hymenoptera, and gives tables for the separation of the families, genera, and species of forms known to occur in Connecticut, together with brief descriptions and records of the distribution of such forms in the State. In collaboration with the author, A. D. McGillivray has prepared the part relating to the superfamily Tenthredinoidea; W. M. Wheeler that relating to the superfamily Formicoidea; C. T. Brues, the superfamily Serphoidea or Proctotrypoidea, and families Cosilidæ and Bethylidæ of the superfamily Vespoidea; and S. A. Rohwer, the superfamilies Sphecoidea and Vespoidea, with the exception of certain groups. The work records 86 families represented by 634 genera and 1,102 species from Connecticut, of which 366 species were originally described from the State. Complete indexes to the plant hosts, insect hosts, and Hymenoptera are included.

Observations on the occurrence of the Argentine ant (Iridomyrmex humilis) in Silesia, F. Pax (Illus. Schles. Monatschr. Obst. Gemüse u. Gartenbau, 4 (1915), No. 3, p. 33; abs. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 3, pp. 97, 98).—The Argentine ant, which is known to occur in the open in Portugal, Bosnia, and Belgium, is reported to have been found in the greenhouse of the Botanic Gardens at Breslau.

On some North American species of Microdon, F. Knab (*Proc. Biol. Soc. Wash.*, 30 (1917), pp. 133-144).—Five new syrphid species are here described.

New chalcid flies from Maryland, II, A. A. GIRAULT (Ent. News, 28 (1917), No. 6, pp. 255-258).—In continuation of the paper previously noted (E. S. R., 36, p. 556) four species and one genus, Blattotetrastichus, are described as new.

A new aphis-feeding Aphelinus, L. O. Howard (Proc. Biol. Soc. Wash., 30 (1917), pp. 77, 78).—Aphelinus lapisligni reared from Aphis bakeri at Forest Grove, Oreg., is here described as new.

The cyclamen mite, W. A. Ross (Agr. Gaz. Canada, 4 (1917), No. 3, pp. 174, 175, fig. 1).—An undescribed species of Tarsonemus was reported by florists in Hamilton, Brantford, and Niagara Falls in the fall, of 1916 as destroying the flowers and flower buds of cyclamen and causing the foliage to curl, resulting in the affected plants being rendered absolutely worthless.

## ANIMAL PRODUCTION.

Physiological effect on growth and reproduction of rations balanced from restricted sources, E. B. Hart, E. V. McCollum, H. Steenbock, and G. C. Humphrey (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 4, pp. 175-198, pls. 15).—In this contribution from the Wisconsin Experiment Station, work previously noted (E. S. R., 26, p. 467) is continued.

The experiment was carried out with grade Holstein heifers weighing from 200 to 400 lbs. The feeding period began in 1910 and continued for two years. It was proposed that one group should receive its nutrients wholly from the corn plant, another from the wheat plant, a third from corn grain and wheat straw, a fourth from wheat grain and corn stover, and a fifth from corn grain and the roughage equally divided between alfalfa hay and wheat straw. In carrying out the work other factors, as the baking of the wheat, the addition of certain mineral elements, etc., were introduced in an attempt to obviate the difficulties encountered.

A physiologically complete ration of corn-grain and corn-stover was not disturbed by altering the calcium-magnesium ratio through the addition of magnesium saits nor by the addition of mineral acids in excess.

A ration from the wheat plant alone did not sustain growth and the animals could not be bred. Blindness ensued, with feeble and emaciated condition and excitability, followed by collapse. The addition of salt did not improve the

ration nor did the baking of the wheat. Additions of butter fat did not uniformly improve the ration. The causes are ascribed to an inherent toxicity of the wheat grains especially resident in the embryo. The addition of a large amount of wheat embryo was found likely to produce an early abortion. From a histological examination of the organs of the animals fed wheat products alone, attention is called to the similarity with conditions in beriberi in man. These animals also showed a low resistance to other diseases, notably anthrax.

Corn grain with wheat straw sustained growth at a slow rate. The offspring, however, were born weak or dead. The addition of salt to this ration made it normal, indicating that it was the needed factor lacking.

With wheat grain and corn stover growth was made but reproduction was only partially sustained, depending apparently on individuality. Where reproduction was successful in the first period, it failed in the second, due to the cumulative effects of the toxins of the wheat.

In the case of corn grain and a roughage made up of one-half each of wheat straw and alfalfa hay excellent growth was maintained and normal reproduction in the first period. In the second gestation period, however, weakness appeared. While this mixture made an improved ration, it was not perfect and might fail through accumulated toxicity.

The experiments indicate that modifications must be made of our present ideas of "balanced" rations and that we must take into consideration other factors as toxicity, a proper balance of salts, and certain growth-promoting compounds of unknown nature.

Some nutritional characteristics of corn, J. T. WILLARD (Kans. Acad. Sci. Bul. 1 (1916), pp. 16).—A paper read at the annual meeting, in which a number of tables of analyses from various sources are shown and data compiled. A popular discussion is given of the corn plant as a factor in nutrition, and various experiments, including recent ones at the Kansas Experiment Station, are quoted.

Feeds and feeding abridged, W. A. Henby and F. B. Morrison (Madison, Wis.: Henry-Morrison Co., 1917, pp. VIII+440, figs. 116).—A condensed edition of the sixteenth edition of Feeds and Feeding (E. S. R., 34, p. 261), to which have been added chapters on the feeding and care of poultry. An appendix contains tables showing the composition, digestible nutrients, and fertilizing constituents of the more important feeds. Each chapter closes with questions covering the subjects noted, and it is sought throughout to adapt the book to the needs of agricultural courses in secondary schools and short courses in agricultural colleges.

Cost of digestible nutrients in principal cattle feeds, H. B. WINTERS (N. Y. Dept. Agr. Bul. 84 (1916), pp. 2147-2164).—The value of available cattle feeds from June 1, 1915, to May 1, 1916, based upon the digestible nutrients, has been computed.

Commercial feeding stuffs, P. H. Wessels et al. (Rhode Island Sta. Insp. Bul., 1917, May, pp. 3-16).—Analyses are reported of various brands of commercial feeding stuffs found for sale in Rhode Island in 1916, including meat scrap, fish scrap, tankage, cottonseed meal, linseed meal, gluten meal, gluten feed, distillers' dried grains, brewers' dried grains, wheat middlings, wheat bran, hominy feed, mixed and proprietary live stock and poultry feeds, ground oats, alfalfa meal, dried beet pulp, flax shives, and alfalfa.

Digest and copy of revised feeding-stuffs law (New Jersey Stas. Circ. 74 (1917), pp. 2-8).—A revision of Circular 10 (E. S. R., 28, p. 364), including the text of the law as amended March 16, 1916.

[Live-stock investigations], A. C. Habtenbower, J. Barbour, and L. B. Barber (Guam Sta. Rpt. 1916, pp. 39-44, 50-53, 54-57, pls. 4, figs. 5).—An effort was

made during the year to improve the live stock of the island by the further importation of pure-bred sires. New methods of feeding were also taken up, and all animals of the station were put upon definite rations.

The work with horses sought to improve the native stock by crossing with Morgan sires. The average weight of native horses is 460 lbs. They are hardier under local conditions, however, than imported animals. By crossing the size has been increased, and the crosses developed appear hardy on native pastures without extra feed. Native pasturage alone will not support Morgan horses. In a feeding experiment with two Morgan horses comparing alfalfa hay with Para grass, the former possessed a superior feeding value, although it can not be fed in Guam in the quantity and as successfully as in colder climates. For the station horses 5 lbs. of alfalfa hay and 40 lbs. of Para grass per day gave good results.

Native bulls average 690 lbs. and cows 512 lbs. The crossbred cattle compare favorably in hardiness with the native cattle, and the improvement by crossbreeding is most satisfactory.

During the year two Berkshire boars were imported. The stock in hand had deteriorated through inbreeding and parasitic infestation. A feeding experiment was carried out with two lots of four pigs each, comparing a ration of breadfruit and coconuts with corn and shorts. The animals were fed for 140 days. The pigs on the breadfruit-coconut ration made an average daily gain per head of 0.388 lb. at a cost of 11.58 cts. per pound. Those on the corn and shorts ration made an average daily gain of 0.45 lb. at a cost per pound of gain of 11.09 cts. Attention is called to the high cost of gain and the necessity of forage crops to lessen the cost. For pasturage Para grass was found to be very satisfactory for hogs, and with a light supplementary ration of breadfruit and coconuts the animals remained in excellent condition.

The work with goats during the year was much hampered by parasites.

The crossbreeding of poultry is showing good results. The best record of six native hens was 42 eggs per year, while that of six hens of the Brown Leghorn-native cross was 127 eggs. In feeding rice hulls to young chicks, death from crop impaction resulted in some cases, and it was found advantageous to use unhulled light rice instead. In a comparative test of brooders, it was demonstrated that for the first six weeks after hatching the chicks should be kept off the ground. An experiment was made comparing an imported grain ration made up of wheat, corn, and oats (2:1:1) with a Guam-grown ration made up of rough rice, a dry mash being used in each case. Two lots of 12 each of Brown Leghorns and two lots of crossbred fowls were employed. The experiment ran from September 1 to June 30. The Brown Leghorns on imported feeds laid 719 eggs, on native feeds 842. The crossbred fowls on imported feed laid 714 eggs and on native feed 915 eggs. In feeding grated coconut to chicks under 6 weeks old, the inclusion of more than 5 per cent in the ration invariably produced diarrhea, while 15 per cent or more caused a total loss of all chicks.

[Animal husbandry studies at the Missouri Experiment Station] (Missouri Sta. Bul. 147 (1917), pp. 21-27, 48).—This progress report includes, among others, the following studies:

The use of nitrogenous concentrates and heavy and light rations of silage for fattening two-year-old steers, by H. O. Allison.—The test indicates that the cost of fattening cattle can be greatly reduced by the extensive use of corn silage with nitrogenous concentrates.

The value of sour milk and beef scrap in rations for growing chicks, and the cost of growing chicks, by H. L. Kempster.—At the end of the first three weeks 100 chicks with skim milk in the ration weighed 21.4 lbs. at a cost of 2.76 lbs. of feed per pound of gain, the beef scrap chicks weighed 15.1 lbs. at a cost of

5.54 lbs. of feed per pound of gain, and the no-milk-or-meat chicks weighed 9.86 lbs. at a cost of 15.1 lbs. of feed per pound of gain. The mortality in the three lots was 13.4, 22, and 34 per cent, respectively.

Live stock of the farm.—V, Pigs and poultry, edited by C. B. Jones (London: The Gresham Publishing Co., 1916, vol. 5, pp. XI+269, pls. 41, figs. 17).—This treats of pigs and poultry, as to breeds, feeds, management, marketing, and diseases.

Live stock of the farm.—VI, Bees, goats, dogs, ferrets, asses, and mules, edited by C. B. Jones (London: The Gresham Publishing Co., 1916, vol. 6, pp. VIII+199, pls. 19, figs. 13).—The treatment is similar to the part noted above.

[Swiss live stock industry], A. Borgeaud, J. Frey, and D. Bouret (Vie Agr. et Rurale, 6 (1916), No. 36, pp. 164–180, figs. 12).—In this special number, devoted to Swiss agriculture, pages 164–175 treat of the cattle industry, breeds of cattle, and cooperation among cattle raisers; pages 176–180, of goats (breeds and breeding).

Statistics of Swiss live stock industry (*Ergeb. Schweiz. Viehzähl, Kanton Zurich, 1916, pp. 31, figs. 2*).—Data covering several years are presented as to the number and kinds of animals owned in the various cantons. From 1911 to 1916 there was practically no change in the number of horses. Cattle increased 1 per cent, and smaller animals over 9 per cent.

Proceedings of the nineteenth and twentieth annual conventions of the American National Live Stock Association (*Proc. Amer. Nat. Live Stock Assoc.*, 19 (1916), pp. 171, pls. 14; 20 (1917), pp. 202, pls. 14).—The proceedings and addresses are reported of these conventions, held respectively, at El Paso, Tex., in January, 1916, and Cheyenne, Wyo., in January, 1917.

Inbreeding, A. B. BRUCE (Jour. Genetics, 6 (1917), No. 3, pp. 195-200).—On the assumption that inbreeding is essentially "self-fertilization" in a greater or lesser degree, and that, in each generation, selfing and mating at random take place in a fixed ratio, the author proposes general formulas to express not only the array but also the genetic constitution of the individuals of which the family under investigation is composed.

Report on cattle feeding experiments conducted at the schools of agriculture and experiment stations at Cedara, Natal, and Potchefstroom, Transvaal (Union So. Africa Dept. Agr. [Pub.] 15 (1916), pp. 40, figs. 22).—The experiments reported were made on from 10 to 16 head of three types of cattle to determine whether a profit could be obtained by using feeds produced on the farm. The feeds covered a wide range of roughage, maize meal, and peanut cake.

With 6-year-old cattle, profits were made by grass fattening, but the addition of maize meal resulted only in a reduction in profits.

The results with 3-year-old cattle indicated that their raising and fattening with local feeds appears to be a remunerative business. It is believed that the future of the beef cattle industry in South Africa will be the fattening of younger cattle of this class.

In experiments with superannuated work oxen with feeds easily produced on South African farms, profits were returned at present prices. Because of the scarcity at present in the London market there was a profit in such cattle where extra feeding had produced a covering of fat. In fattening the old oxen better gains were obtained with animals possessing a dash of improved blood.

Feeding experiment with oil-extracted palm kernel meal and undecorticated earthnut cake, J. Hendrick and W. J. Profit (North of Scot. Col. Agr. Bul. 21 (1916), pp. 10).—In continuation of work previously reported (E. S. R., 34, p. 566), an experiment was carried out to compare the value of oil-extracted palm kernel meal and undecorticated peanut cake with linseed cake, and also

to determine whether a home-grown product, crushed oats, could be profitably substituted for these imported feeds. The meal used was extracted with chemical solvents and contained less oil than the cake which was extracted under pressure.

Thirty-two crossbred bullocks in lots of 8 each were fed for 84 days, divided into periods of 28 days each. Turnips and straw were used as roughage. In addition, lot 1 received linseed cake and crushed oats; lot 2 peanut cake and crushed oats; lot 3 palm kernel meal, crushed oats, and a small portion of locust bean meal to induce the animals to eat the ration; and lot 4 crushed oats. The manurial value was deducted from the cost of the feed in each lot. On linseed cake bullocks made an average gain of 2.31 lbs. daily, on peanut cake 1.99 lbs., on palm kernel meal 2.15 lbs., and on oats alone 1.98 lbs. The net cost of gain per hundredweight was for lot 1, 48s. (\$11.66); lot 2, 46s. 3d.; lot 3, 51s.; and lot 4, 50s.

Peanut cake gave the best monetary returns and was eaten readily. Crushed oats alone, while costing more than the other feeds, was considered a satisfactory concentrate with turnips and straw.

Ageing Egyptian cattle, Mohammed Askab (Agr. Jour. Egypt, 6 (1916), pp. 73-78, pls. 12).—A discussion of methods of determining the age, with 17 drawings of the teeth and mouth, of Egyptian cattle.

Live stock of the farm.—IV, Sheep, edited by C. B. Jones (London: The Gresham Publishing Co., 1915, vol. 4, pp. X+252, pls. 38, figs. 18).—Chapter 1 deals with sheep farming in the British Isles, the development and distribution of breeds, and statistics. Chapter 2, prepared by various authors, gives a description of the different breeds. Chapters 3, 4, and 5 are devoted respectively to profitable sheep farming, general management and feeding, and diseases.

Sheep production, P. V. GARCÍA (Bol. Min. Agr. [Argentina], 20 (1916), No. 5-6, pp. 391-462, figs. 32).—A statistical discussion of the production and exportation of sheep from Argentina from 1895 to 1915.

The number of sheep in the country has greatly decreased in this period, especially among the lower grades. The quality of the animals has improved, however, both as to wool and meat. The average weight of carcasses exported from 1896 to 1915 shows a gradual increase from about 23 to above 27 kg. (50.6 to 59.4 lbs.).

Sheep and wool for farmers. Crossbreeding experiments, J. W. Mathews (Agr. Gaz. N. S. Wales, 27 (1916), Nos. 5, pp. 325-334, figs. 6; 6, pp. 397-407, fig. 1).—This experiment, which is being continued, compares the crossing of wool and mutton type sheep. The work reported, covering five years, gives the results in crossing Lincoln, Leicester, and Border-Leicester rams with Merino ewes. The number of ewes employed was 218.

Exclusive of lambs, the average body weights of the three crosses for all ages were as follows: Lincoln-Merino 107 lbs. 11½ oz., Leicester-Merino 106 lbs. 6½ oz., Border Leicester-Merino 117 lbs. 2 oz. In wool weight, the Lincoln cross wethers average 1 lb. 4 oz. over the Leicester cross and practically 1 lb. over the Border-Leicester cross. With the ewes the differences were 1 lb. 1 oz. and 10 oz., respectively, in favor of the Lincoln.

The wool averaged in price for the whole period as follows: Lincoln-Merino 13.19d. (26.2 cts.) per pound, Leicester-Merino 13.71d., and Border Leicester-Merino 13.89d.

Horses, R. Pocock (London: John Murray, 1917, pp. X+252).—The origin, history, and future of the horse are treated by a practical man who has gleaned his knowledge from the western plains and in war.

Horse breeding and horse racing, J. C. EWART (Nature [London], 99 (1917), No. 2487, pp. 346, 347).—The author points out the necessity for the preservation of the Thoroughbred horse and for the improvement of the breed for military and other purposes. As race horse breeding implies racing, the plea is made for the continuance of such racing as may be required to test the value of the stallions and mares now at stud in the United Kingdom.

A history of the Percheron horse, compiled by A. H. Sanders and W. Dinsmore (Chicago: Sanders Publishing Co., 1917, pp. 602, pls. 131, figs. 10).—In this history of the origin, evolution, development, and distribution of the modern heavy draft type of Percheron horses the effort has been made to throw new light upon the foundation history of the type in the district of the Perche in France. Data for this part of the work were obtained from books, records, and documents in the Government archives at Paris, including the official registration and inspection entries of stallions bought for the French Government stud at Le Pin, and lists of stallions approved and subsidized by the Government prior to the Stud Book in the Perche. The evidence thus obtained tends to show that the Percheron horse has existed as a distinct type from very ancient times, and that Arabian blood has played very little part in the production of the latter-day type of the breed.

A detailed account is given of the introduction and dissemination of the breed throughout the United States, to which is appended a symposium reflecting the views of contemporary importers and breeders on the selection, feeding, and general management of stallions, brood mares, and foals.

The diastatic action of saliva in the horse, R. J. Seymour (Amer. Jour. Physiol., 43 (1917). No. 4, pp. 577-585).—Both the mixed and the isolated secretions of the parotid and submaxillary glands of the horse were found to contain a diastase capable of converting starch into sugar. The diastase is indicated as being extremely feeble, requiring at least five hours for the conversion of boiled starch. The action of the diastase (pytalin?) was not increased by aeration, by acidifying, or by exposing to the action of weak alkalies.

The saliva of the horse was found to be inactive on cellulose and on sucrose. No evidence of the secretion of a zymogen with a subsequent conversion into active ptyalin was observed. "Salivary secretion may occur in the horse without mastication by stimulation with chemical substances, with an apparent augmentation through the psychic effect of the sight of food; the greatest flow occurs when the horse is permitted to masticate food material." Potassium sulphocyanid was not found in the saliva.

See also previous notes by Palmer (E. S. R., 36, p. 82) and by Palmer and others (E. S. R., 37, p. 681).

Sex-linked inheritance of spangling in poultry, G. Lefevre (Abs. in Anat. Rec., 11 (1917), No. 6, pp. 499, 500).—A series of experiments has been carried out at the Missouri Station for the purpose of determining the mode of inheritance of spangling in poultry (E. S. R., 35, p. 867).

The initial crosses were made reciprocally between Silver Spangled Hamburgs and Brown Leghorns, and the material used for the analysis has been obtained from twelve different matings. The conclusion has been reached that spangling is determined in inheritance by a distinct factor which behaves in a typically sex-linked fashion, the cocks being homozygous and the hens heterozygous for it in Silver Spangled Hamburgs. When spangling is introduced through the male, both sexes in the F<sub>1</sub> generation show spangles, while the reciprocal cross gives only spangled males, the females being nonspangled and incapable of transmitting the pattern.

It has been further shown that the expression of spangling may be greatly modified, or even entirely obscured, by the action of other factors, especially factors for black pigmentation, which, however, segregate independently of the factor for spangling. The independence of the spangling factor is indicated by the fact that, after segregation and recombination of the several factors concerned, some individuals are extracted in which all disturbing factors are absent and the spangled pattern is exhibited in its original purity. A number of such birds have been obtained from different matings, and these now breed as true to spangling as do the Silver Spangled Hamburgs themselves.

Mendelian inheritance in poultry, G. Lefevre (Abs. in Missouri Sta. Bul. 147 (1917), pp. 47, 48).—This is another abstract of the data reported above.

The structure of the fowl, O. C. Bradley (London: A. & C. Black, Ltd., 1915, pp. XII+153, pls. 17, figs. 28).—A concise descriptive anatomy of the fowl, with a chapter on the embryology of the chick.

Studies on the physiology of reproduction in birds, I-VII, O. RIDDLE ET AL. (Amer. Jour. Physiol., 41 (1916). No. 3, pp. 387-437; 42 (1916), No. 1, pp. 151-162).—In this series of articles, the first seven of which are here noted, results are given of studies of the physiology of avian reproduction in relation to the problem of heredity and sex.

I. The occurrence and measurement of a sudden change in the rate of growth of avian ova, O. Riddle.—Continuing studies already noted (E. S. R., 26, p. 164), it has been shown that when the occurrence of the fowl reaches a diameter of about 6 mm. it increases its previous rate of growth to a rate nearly 25.8 times higher. The transition from the one rate to the other is made in a single day and sharply marks off the type of substance accumulated in the ovum. Under the slower rate this is white yolk. Under the greatly increased rate the yellow yolk is produced. The increased rate of deposition of yolk materials is accompanied by a pronounced alteration in the growth and activity of the membrane (follicular) which surrounds the ovum. A comparable change in growth rate occurs generally in other avian and sauropsidan eggs.

II. On the chemical composition of white and yellow egg yolk of the fowl and pigeon, Adelaide A. Spohn and O. Riddle.—By taking advantage of the fact that the ova of the fowl consist wholly of white yolk until they begin their final period of rapid development (see above) the authors were able to prepare samples of the two kinds of yolks for analysis. The results of the analyses of two samples of white yolk and of six samples of yellow yolk of the common fowl demonstrate that the two forms of yolk are strikingly different substances, and that the white yolk much the more nearly approximates the composition of small holoblastic eggs, and of living undifferentiated tissue generally. The ovarian egg (yellow yolk) of the fowl contains little more than 45 per cent of water. The solids of the fowl's egg contain 20.6 per cent of phosphatids, 49.5 per cent neutral fat, and 28.4 per cent protein.

Analyses were also made of two samples of yellow yolk of the jungle fowl and five samples of yellow yolk of the common pigeon. The results indicate that the yellow yolk of the jungle fowl has probably a lower lipoid and a higher protein content than the yolk of domestic fowls. The yellow yolk of the pigeon differs most from that of the fowl in its much higher moisture value, but probably differences in the amount of alcohol-soluble and protein materials also exist. The yellow yolk derived from different orders, genera, and species of birds probably varies more in the amount of water than in other fractions, but the yellow yolk from birds of different orders is relatively much alike as compared with yellow and white yolk from the same individual bird.

III. On the metabolism of the egg yolk of the fowl during incubation, O. Riddle.—In this study on the changes in the egg yolk during incubation the

attempt was made to determine, by isolation and chemical analysis of the yolks of eggs subjected to various periods of incubation, the relative rates at which the various constituents of yolk are removed and utilized by the embryo.

A differential utilization of the elements of yolk prior to the twelfth day of incubation has not been shown to occur. A study of the unmetabolized yolk of 12, 18, and 20 day stages shows that after the twelfth day the phosphatids are utilized more rapidly than the neutral fats, and the neutral fats are utilized faster than the proteins. This order of utilization of these substances persists during the 18 to 20 day period when the embryo's sole source of protein is the protein of the yolk. The moisture value of the yolk undergoes very considerable fluctuations during incubation. At the twelfth day it is about 9 per cent higher than in fresh undiluted yolk. At the eighteenth day it has fallen to near the value for fresh yolk. At the very end of incubation this value probably rises considerably. Two forms of semisolid yolk bodies which are occasionally present in final stages of incubation were found to be wholly unlike in their chemical composition. Yolk resorbed by the follicle which secreted it shows a more rapid utilization of the phosphatids (lecithin), the neutral fats are utilized at a somewhat slower rate, while the proteins are metabolized more slowly than either the phosphatids or neutral fats.

IV. When a gland functions for the first time is its secretion the equivalent of subsequent secretions? O. Riddle and Adelaide A. Spohn.—A comparison was made of the composition of the albumin secreted by the pigeon's oviducal glands in their initial functionings with that of albumin secreted later by these glands.

Albumin produced in initial efforts contains a smaller percentage of water and a higher percentage of alcohol-ether-insoluble substance. During a few of the earlier functionings of the oviducal glands, there probably occurs a gradual change from the initial lower percentage of water to the later higher percentage of water. Partial analyses of the albumin of the pigeon's egg are recorded and one source of variation in the moisture value of this albumin has been identified. The amounts of alcohol-ether-soluble substance, and of inorganic matter probably do not vary widely nor consistently. The amount of water in the egg albumin of the pigeons studied shows no consistent variation in respect to summer and winter. The earliest secretion of the albumin-secreting gland of the pigeon's oviduct is, in several respects, a rather close approximation to the later products of the gland.

V. The effect of alcohol on the size of the yolk of pigeon's egg, O. Riddle and G. C. Basset.—In the studies here reported two common pigeons, two blond Ring doves, and three hybrids were used. Four of the birds were given alcohol by inhalation daily, with certain exceptions, for four months, and three for only two months. It was found that the yolks produced during the alcoholization period by these birds become smaller than during the prealcoholization period. This decrease occurs even during the season when the yolks of untreated birds normally grow larger than in the earlier period. Yolks produced during a few weeks or months after the alcoholization period are smaller than normal.

VI. Sexual differences in the fat and phosphorous content of the blood of fowls, J. V. Lawrence and O. Riddle.—Results are given of a study of the amount of fat and phosphorus in the blood, in relation to sex and sexual activity, in the common fowl.

The blood plasma of female fowls is found to be richer in alcohol-soluble substance and phosphorus than is the plasma of the male. The blood plasma of the sexually functioning female fowl contains more alcohol-soluble substance and more phosphorus than does the plasma of fowls with temporarily inactive ovary. The male, the nonlaying female, and the actively laying female fowl are three natural groups of fowls when these are considered from the standpoint of the

fat and phosphorus content of the blood-plasma. The relative distribution of phosphorus in the alcohol-soluble and alcohol-insoluble fractions of the blood plasma is also different for these three groups of fowls. The differences here observed and measured are quantitative.

VII. Variations in the chemical composition of reproductive tissues in relation to variations in functional activity, O. Riddle and J. V. Lawrence.—
The membranes which immediately surround different sizes of growing occytes of the fowl were analyzed. The phosphatids of all the membranes analyzed were found to exist in amounts relatively large in proportion to the neutral fats. The greatest disproportion of phosphatids to neutral fats, and the largest amounts of phosphatids, apparently were found in the membranes surrounding occytes from 5 to 6.5 mm. in diameter.

Analyses were also made of active and relatively inactive shell glands and albumin-secreting glands. In the shell glands the total alcohol-ether soluble substance is greatest when the gland is inactive and the moisture is greatest when the gland is active. While the alcohol-ether soluble phosphorus does not differ consistently in the active and inactive shell glands, it is perhaps higher in the active glands. In the albumin-secreting glands the alcohol-ether soluble phosphorus is much increased under inactivity. The percentage of water is somewhat larger in the active than in the inactive albumin-secreting glands.

The results are thought to indicate that an increase in the physiological activity of a tissue is accompanied by an increase in its phosphatid content.

A study of the incubation periods of birds, W. H. Bergtold (Denver: The Kendrick-Bellamy Co., 1917, pp. 109).—The author reviews the reasons assigned for the variations in the incubation periods of birds which are based on passive conditions, such as an anatomical character (size of body), a histologic character (size of egg), and effects which merely retard or suspend embryonic development.

Attention is also called to a factor that has received little attention, namely, bird temperatures. The importance of a study of bird temperatures is urged because it has been demonstrated that there is an optimum incubation temperature, which perhaps varies with different species. He puts forth the tentative conclusion that "a bird's temperature determines or fixes the time length of its incubation period, and that only an abiding change in the bird's temperature can permanently alter the time length of its incubation period."

The molting of fowls, R. F. Ibvin (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 10, pp. 4).—A discussion of the molting of fowls from which the conclusion is drawn that it is better to feed the birds liberally during the period, and that no gain is made in forcing the molt by starving.

Protein feeds for laying hens, H. L. Kempster (Missouri Sta. Circ. 82 (1917), pp. 11, figs. 4).—In continuation of work already noted (E. S. R., 35, p. 773) three 10-bird pens of White Leghorn hens were fed from November 1, 1915, to October 31, 1916, to test the effect of sour milk on egg production. The rations of the different pens were identical with those of the previous year. The average number of eggs per hen laid by the no-meat-or-milk pen during the year was 59.7, by the beef-scrap fed pens 133.6, and by the sour milk fed hens 126.9. On the price basis of the previous year there was a loss of 5 cts. per hen on the no-meat ration, a profit of \$1.04 per hen on the beef-scrap ration, and a profit of 92.4 cts. per hen on the sour-milk ratio.

In another test covering the same period linseed meal, gluten meal, and cottonseed meal were compared as sources of protein for laying hens. In this test, which involved three pens of 10 White Leghorn hens each, the birds were fed a mash composed of equal parts by weight of bran, shorts, corn meal, and

one of the above protein feeds. During the year the linseed meal pen laid an average of 64.9 eggs per hen, the gluten meal fed hens an average of 63.8 eggs each, and the cottonseed meal fed hens an average of 66 eggs each. The hens did not relish the linseed meal mash as much as they did the other mashes. "So far as could be observed the hens in all pens were in perfect health throughout the entire experiment with vegetable proteins. No deleterious effects were observed in the use of the cottonseed meal.

"Beef scrap and sour milk are the most economical methods of supplying protein to laying hens. Protein concentrates of vegetable origin alone did not materially increase egg production—It is poor economy not to furnish the laying hen a protein concentrate of animal origin."

The poultry keeper's manual, G. Allman (West. Aust. Dept. Agr. Bul. 47 (1916), pp. 96, pl. 1, figs. 25).—A practical treatise on the growing of poultry and their diseases and remedies therefor.

Commercial egg farming, S. G. Hanson (London: Constable & Co., [1916], pp. 62, pls. 8).—Practical methods applying to English conditions are set forth.

Poultry standards in their relation to utility, J. Hadlington (Agr. Gaz. N. S. Wales, 28 (1917), No. 3, pp. 208-216, figs. 6).—Standards are given for the White Leghorn, Black Orpington, and Rhode Island Red breeds of fowls, together with photographs which represent the author's interpretation of the utility character of these breeds. A plea is made for a revision of the scale of points for these breeds set out in the English standards.

American squab culture, E. H. Eggleston (Chicago: Author, 1916, pp. 191, figs. 37).—A practical treatise for those in the business of raising squabs for market. The subjects treated are breeds, breeding, marketing, pests and ail ments, houses, and equipment. Considerable miscellaneous information is also given on various problems likely to arise in the prosecution of the industry

Squab culture, D. R. Wood (Terre Haute, Ind.: The Indiana Squab Co., 1916, pp. 71, figs. 17).—Practical instructions in raising and marketing squabs.

The raising and care of guinea pigs, A. C. SMITH (Kansas City, Mo.: Author, 1915, pp. 35, figs. 5).—This treats of the rearing, marketing, and uses.

The rabbit: How to select, breed, and manage the rabbit for pleasure or profit, W. N. RICHARDSON (Syracuse, N. Y.: Clarence C. DePuy, 1916, 7. ed., pp. 64, figs. 14).

## DAIRY FARMING-DAIRYING.

Cattle breeding problems and their solution, R. Pearl (Ann. Rpt. Comr. Agr. Maine, 14 (1915), pp. 215-242, figs. 4).—Progress reports are presented on the following lines of work being conducted at the Maine Station:

The study and analysis of milk records.—In a study of the relation of milk flow to age in dairy cattle (E. S. R., 32, p. 575), a comparison was made of American and Scotch Ayrshires in respect to milk production. Comparing the mean weekly yields of American Advanced Registry and Scottish Milk Records Society Ayrshire cows, it was found that the American cows outyielded their Scottish sisters by 1.23 gal. per week in the 2-year-old class, 2.92 gal. in the 3-year-old class, 2.24 gal. in the 4-year-old class, and 1.76 gal. in the "mature" class. The mature American cows produced about 9 per cent more milk than the mature Scotch cows. The question is raised whether the American standard is high enough to get the best results in the direction of breed improvement.

For the purpose of comparing herds made up of cows of various ages and stages of lactation the author has constructed a dairy efficiency table in which it is assumed that cows from five to seven years of age and during the first month of lactation are 100 per cent efficient, and that cows of any other age

or stage of lactation are less than 100 per cent efficient. The manner in which the table is to be used is shown by examples.

The study of inbreeding in dairy cattle.—A preliminary report is made of a study of inbreeding in American Jersey cattle. Tabulated data and diagrams are presented showing the coefficients of inbreeding for random samples of the general population of both Jersey bulls and cows and of samples of the animals in the Register of Merit. From these it is concluded that American Jersey cattle at the present time may be said, in general and on the average, to be about one-half as intensely inbred, when account is taken of the eighth ancestral generation, as would be the case if continued brother X sister breeding had been followed. That, in general and on the average, Register of Merit animals are less intensely inbred than the general population of Jersey cattle.

Physiology of cattle breeding.—In a study of the normal duration of oestrum in cattle it was found that of 834 successful services which are tabulated over 79 per cent occurred within 10 hours after the discovery of heat. No significant differences appeared between the distributions for the different breeds.

A study of 712 cows from the herds of about 150 leading dairymen of Maine shows that on the average these cows were dry about 4 days short of 2 months prior to calving. About 14 per cent of them were dry more than 79 days and about 29 per cent were dry less than 40 days.

In a study of the age of cattle used as breeders by dairymen in the State, it was found that of 967 calves included in the statistics 58.9 per cent were sired by bulls less than 3 years of age at time of service. Less than 15 per cent of the calves were sired by bulls 5 or more years old. The bearing of these facts on the progress in dairy cattle breeding is evident, since it is impossible to test the milk producing capacity of a bull's daughters before he is 3 years old. The average age of breeding cows in the study was approximately 5.5 years. Out of 878 calves 166 were the first calves of helfers. The average age of these helfers when successfully served for these first calves was approximately 1 year and 7 months. Three-quarters of the helfers were successfully served for their first calves before they were 2.1 years old.

The Kerry: Its advantages under present conditions, Cheviot (Mark Lane Express, 118 (1917), No. 4483, pp. 206, 207, figs. 2).—The advantages of the Kerry cattle as compared with the dairy type of Shorthorns and other dairy breeds under present war conditions are pointed out, and notes are given on the origin of the Kerry breed and of the type of the breed known as Dexter Kerry.

Studies from the survey on the cost of market milk production, K. B. Musser, G. C. White, B. A. McDonald, and H. F. Judkins (Conn. Agr. Col. Ext. Serv. Bul. 7 (1917), pp. 27).—Results are given of a survey of 193 representative dairy farms in Connecticut made for the purpose of determining the cost of producing milk for the year ended April 30, 1917, and for the month of April, 1917.

It was found that the cost of producing milk on 178 of these farms for the year ended April 30, 1917, was 5.53 cts. per quart. There was an average loss for the year per cow for the 178 farms of \$18.42. The cost of producing milk on 179 farms for the month of April, 1917, was 6.29 cts. per quart, with labor at the yearly rates.

The 28 highest-producing herds produced milk on the average for 2.06 cts. per quart below the 25 lowest-producing herds. The greatest percentage of pure-bred bulls and milk records were in the 28 herds with the highest-producing cows, while the smallest percentage was in the 25 lowest-producing herds. The 28 highest-producing herds showed a profit above the net cost of production of \$10.86 per cow per year, while the lowest-producing herds showed a loss of \$33.75. The average milk production of the 3,258 cows on these 178 farms was

6.009 lbs. per year, whereas the general average for the State is estimated at 5.500 lbs.

Tabulated data show detailed cost data for each farm, and averages for each county in the State.

The milk supply—a suggestion, R S. Williams and Elfeida C. V. Cornish (Cambridge, England: University Press, 1917, pp. 10, figs. 3).—The authors call attention to the present unsatisfactory method of handling the milk supply of cities, and suggest a scheme of handling raw milk. The essentials of this plan are that the milk be taken from healthy cows under cleanly conditions, cooled within three hours after milking, either at the farm or at factories within reach of a group of farms, put into sterile hermetically sealed cans, shipped in refrigerator cars to the destination, and kept cool until delivered to the consumer.

Manual of milk products, W. A. STOCKING (New York: The Macmillan Co., 1917, pp. XXVII+578, pls. 16, figs. 90).—In this manual the author has brought together the more important findings in regard to the handling of dairy products. The subject is treated under the headings of milk secretion, the chemical composition of milk, factors that affect the composition of milk, physical properties of milk, the testing of milk and cream, market milk, certified milk, butter making, cheddar cheese, fancy cheeses, farm dairying, condensed and powdered milk, fermented milk, ice-cream making, and the relation of bacteria to dairy products.

Modern pasteurization at low temperature, J. VANDERLECK (Agr. Gaz. Canada, 4 (1917), No. 7, pp. 614-619).—Results are given of experiments conducted by the department of bacteriology of Macdonald College in which milk was pasteurized at different temperatures in a small pasteurizer on a dairy farm. Data bearing on the subject obtained in the course of an investigation of the milk supply by municipal authorities in the district of Montreal are also tabulated.

The author concludes that "raw milk produced under sanitary conditions and pasteurized at 145° F. for 20 minutes contained virulent coli bacteria, causing enteritis in infants. Pasteurized milk of reliable concerns contained during the summer so many coli bacteria that it was bound to have a harmful effect. Milk pasteurized at 145° for 30 minutes by numerous small concerns contained so many coli bacteria (virulent gas producers) that the milk was unfit for consumption. In milk pasteurized at 152° the coli bacteria had lost their virulence and most of them were killed. In milk pasteurized at 152° in the proper way, the food value is unimpaired, and as the cream will not rise to the top it will be impossible to reduce its value as a beverage by skimming the cream off."

Cause and prevention of mold on butter, E. G. Hastings (*Proc. Wis. Butter-makers' Assoc.*, 16 (1916), pp. 145-152, fig. 1).—In this popular summary of the cause and prevention of mold on stored butter, the author gives results of tests of bleaching powder and hot water on mold spores.

In a 1:3,330 solution of bleaching powder or chlorid of lime, mold spores were killed after an exposure of 10 minutes, and in solutions of 1:16,550 to 1:33,330 after an exposure of 20 minutes. Trials of the same mixture of spores resulted in the death of all spores in water heated to 131 and 140° F. An exposure of 15 minutes in water with a temperature of 122° failed to kill the mold spores. The author states that butter tubs and liners should be placed for a few minutes in water heated to 150° and as a further precaution the cream should also be pasteurized. If only mold spores are present salt is likely to prevent their germination.

Minnesota creameries; cheese, ice cream, and canning factories (St. Paul, Minn.: Minnesota Dairy and Food Dept., 1916, pp. [4]+69, figs. 15).—Dairy sta-

tistics for the State are tabulated and lists are given of Minnesota creameries and cheese, ice cream, and canning factories.

Siberian butter and cheese (N. Y. Produce Rev. and Amer. Cream., 44 (1917), No. 14, pp. 550, 552, 554).—In this article, which is taken from the Weekly Bulletin of the Canadian Department of Trade and Commerce, it is stated that the butter industry of Siberia began with the introduction of ratiway transportation in 1894. The growth of the industry is one of the chief features of the economic development of the country. In 1913, 72,500 tons of butter was exported from Siberia to Western Europe.

Attempts are also being made in an experimental way to develop the Cheddar cheese making industry. These are meeting with success, and on account of the natural advantages of the country for cheese making it is thought this industry will rapidly grow in importance.

Notes are given on the growth of cooperative enterprises and on the effect of the European war on the butter and cheese industry of Siberia.

Cheese making on an Irish farm, Mabel O Brien (Better Business, 2 (1917), No. 3, pp. 214-225).—This is an account of how an Irishwoman found cheese making both pleasant and profitable on a dairy farm located too far from market for the sale of whole milk.

Experiments on the preparation of homemade rennet, A. Todd and ELFRIDA C. V. Cornish (Jour. Bd. Agr. [London], 24 (1917), No. 3, pp. 307-312).—Results are given of experiments on the home preparation of rennet from calves' stomachs, the method used being a modification of that already noted (E. S. R., 36, p. 378).

By the method described rennet extracts approximating in strength commercial rennet were often obtained. These extracts retained their coagulating properties for a period of several months, and often increased in strength during storage. The number of lactose-fermenting organisms in the extracts decreased with time. Several kinds of cheeses made by the use of rennet so prepared ripened normally and were of good quality.

Experiments with pepsin to replace rennet, D. W. Stevart (Jour. Bd. Agr. [London], 24 (1917), No. 3, pp. 313-315).—An attempt was made to prepare a pepsin solution which would keep fairly well and give results similar to those obtained with standard rennet extract. The pepsin solution was prepared by mixing 4½ parts by weight of a 1:3,000 solution of pepsin, 1 part of boric acid, and 10 parts of salt to 50 parts of water. In cheese-making experiments this pepsin solution compared favorably with rennet extract when well-ripened milk was used, but when the milk was ripened to a less extent the time of coagulation was much longer with the pepsin than with the rennet.

The results of another test indicate that 1 oz. of soluble pepsin powder will curdle only 75 gal. of sweet milk.

#### VETERINARY MEDICINE.

[Veterinary handbooks] ([Portland, Orcg.]: Vet. Sci. Assoc. Amer., 1917, pp. 171; pp. 75, pl. 1; pp. 91, pl. 1; pp. 87, pls. 7; pp. 123, figs. 4).—The first of these handbooks, dealing with Veterinary Medicines, Their Actions, Uses, and Dose, is by G. F. Korinek. The other four, consisting of (2) Notes on Diseases of Cattle, Cause, Symptoms, and Treatment; (3) Notes on Diseases of the Horse, Cause, Symptoms, and Treatment; (4) Notes on Veterinary Anatomy; and (5) Notes on Diseases of Swine, Sheep, Poultry, and the Dog, are by C. J. Korinek.

[Diseases and parasites of live stock], L. B. BARBER (Guam Sta. Rpt. 1916, pp. 44-49, 53, 57, 58, pl. 1, figs. 4).—Acacia farnesiana known as aroma and

Andropogon aciculatus known as "enefuk" are troublesome to horses allowed to run in pastures. The thorns of the former plant cause local inflammation that results in the falling out of the hair, leaving raw sores, or the skin drying and peeling off, leaving a disfigured appearance, while the adherent awn of the latter plant causes conjunctivitis.

Use of the arsenical dip kept the cattle free from ticks, which was found impossible through picking and the oil and kerosene treatment. The importance of keeping the stock free from ticks is emphasized by the work of the year. Charts of the temperatures of four animals suffering from tick infestation are included.

Brief mention is made of the kidney worm (Stephanurus dentatus), a lungworm (Metastrongylus apri), and a cecum worm (Trichuris crenata) in swine, the first two of which were described in detail in a previous report of the station (E. S. R., 35, p. 877). Infestation by the cecum worm results in emaciation and a rough, scaly skin, and diarrhea is present in the early stages. Post-mortem examination shows the mucus surface of the large intestines, especially that of the cecum, to be covered with a thick yellowish crust, the removal of which exposed many pitted ulcers, particularly in chronic cases. The parasites in many instances show through the serous coat of the intestines, and a marked cirrhosis of the liver is generally present.

The nodular worm (*Esophagostomum columbianum*) and the fourth stomach worm (*Hæmonchus contortus*) appeared in the station herd of goats and caused the death of several kids. But few of the chicks in the station flock were lost during the year from diseases or intestinal parasites. A list of 7 external and 15 internal parasites collected, based upon identifications by the Bureau of Animal Industry of the U.S. Department of Agriculture, is included.

[Report of the veterinary department], J. W. Connaway and A. J. Durant (Missouri Sta. Bul. 147 (1917), pp. 54-57).—Continuing the study of hog cholera and the factors concerned in immunity against the disease (E. S. R., 35, p. 878), a preliminary investigation indicated that "no relation exists between the complement-fixation reaction and the potency of the antihog-cholera serum, and that the reaction observed was due to other immune bodies than the specific immune bodies of hog cholera." It is indicated, however, that these conclusions should not be accepted as final until proved by further work.

The contagious abortion investigations were continued in cooperation with the dairy husbandry department and a number of cattle breeders in various parts of the State. Of 42 herds tested during the year for contagious abortion by the complement-fixation test, 31 proved to be infected. Of 638 animals tested, 212 yielded a positive reaction. Data on the question of the transmission of contagious abortion infection from immune positive-reacting dams to their apparently healthy offspring in utero or subsequent to birth through infected milk and the permanency of this infection in the offspring are submitted. While it is considered that more complete data will be necessary for final conclusions, from the data at hand it is provisionally concluded that "the probability of the abortion infection passing from an immune positive-reacting dam to the calf in utero is not great; or, if such apparently normal calf is infected at birth, the abortion infection is probably not conserved in its tissues until the first breeding period. Moreover, the danger of the permanent transmission of abortion infection to the calf through raw milk is small."

Annual report of proceedings under the diseases of animals acts, the markets and fairs (weighing of cattle) acts, etc., for the year 1916, A. W. Anstruther (Bd. Agr. and Fisheries [London], [Vet. Dept.], Ann. Rpts. Proc. 1916, pp. 28).—This reports upon the occurrence of and control work with footand-mouth disease, of which there was one outbreak, and hog cholera during the

year. In hog-cholera work the serum treatment was resorted to frem June 25, after which date slaughter in suspected outbreaks was limited to animals needed for diagnostic purposes.

Report on operations of the veterinary sanitary service of Paris and the Department of the Seine during the year 1915, H. MARTEL (Rap. Opér. Serv. Vét. Sanit. Paris et Dépt. Seine, 1915, pp. 161, figs. 17).—This is the usual report (E. S. R., 35, p. 279) giving a detailed account of the work of the year.

Annual report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, for the year 1915-16, A. SMITH (Ann. Rpt. Bengal Vet. Col. and Civ. Vet. Dept., 1915-16, pp. 4+II+5+VIII+3).—This is the usual annual report (E. S. R., 35, p. 483).

Animal diseases regulations with notes on diagnoses, F. E. LIONNET (Dept. Agr. Mauritius, Gen. Ser., Bul. 7 (1916), pp. 26).—The regulations in force in Mauritius against animal diseases, which were completely remodeled in 1915, have been brought together in this report. Short notes on the diagnoses of the various infectious diseases specified in the regulations are included.

Manure disposal as a factor in the control of parasitic diseases of live stock, M. C. Hall (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 5, pp. 675-678).—The author calls attention to the fact that the proper disposal of manure is the first step to be taken in the control of parasitic infestation of live stock.

The poisonous properties of the two-grooved milk vetch (Astragalus bisulcatus) (Wyoming Sta. Bul. 112 (1917), pp. 59-67, fig. 1).—This brief preliminary report upon the two-grooved milk vetch, presented at this time in order to warn stockmen of the poisonous nature of the plant, consists of two parts, the first (pp. 59-65), by O. A. Beath, dealing with the chemical properties of the plant; and the second (pp. 66, 67), by E. H. Lehnert, with its physiological effect, etc.

Milk vetch, which grows on the plains and in the valleys throughout the Rocky Mountain region, appears during the month of May and goes to seed the latter part of July. A description and an analysis of the plant by Knight, Hepner, and Nelson have been previously noted (E. S. R., 20, p. 135). The plant has proved to be poisonous to cattle, from 80 to 90 per cent of the affected animals dying, and suspicion is held regarding its effect upon sheep. It was found that water easily removes the active poison from green or air-dried material, and that all parts of the plant contain poison with a slight excess in the leaves. The poison is neither precipitated by basic acetate of lead nor decomposed at the boiling point of water. It is nonalkaloidal, and the fact that it can be deprived of its toxicity by boiling with dilute acids indicates its probable glucosidic character. A definite crystalline substance has been isolated, giving chemical reactions common to glucosids. Thus far no chemical antidote has been obtained, but, as indicated by the physiological action of the poison, drugs that stimulate the heart and nervous system should prove beneficial in the case of vetch poisoning.

Active immunization with sensitized and nonsensitized bacteria, H. F. Swift and R. A. Kinsella (*Proc. Soc. Expt. Biol. and Med., 14 (1917), No. 6, pp. 120-122*).—In the experiment noted four types of vaccine were studied, plain stock vaccine killed at 56° C., sensitized stock vaccine killed at 56°, freshly prepared sensitized vaccine killed at 56°, and an alcohol precipitate of sensitized vaccine. Type I pneumococcus was used in all the vaccines. Mice, guinea pigs, and rats were used as experimental animals, the rats being found the most satisfactory for comparative studies.

The results showed that in from 6 to 10 days after the last immunizing dose there was a higher degree of immunity in the plain vaccine series, but this fell off rapidly. In the series immunized with freshly sensitized vaccine the im-

munity, though present, was less marked early, but increased after from 12 to 16 days. No parallelism was observed between the degree of active immunity and the amount of agglutinin and bacteriotropin in the serum of the immune rats. Agglutinin was demonstrated only in the serum where plain stock vaccine killed at 56° was used. Bacteriotropins were much stronger in the serum of animals treated with this vaccine than in the serum of animals treated with freshly prepared sensitized vaccine killed at 56°. This indicates that "animals may possess a high degree of active immunity and still show practically no antibodies in their serum." It is suggested "that the immunity is due in part to a tissue immunity and not due entirely to antibodies circulating in the blood serum."

Toxin and antitoxin of and protective inoculation against Bacillus welchii, C. G. Bull and Ida W. Pritchett (Jour. Expt. Med., 26 (1917), No. 1, pp. 119-138).—"Antitoxic serum prepared from a given culture of B. welchii is neutralizing for the toxins yielded by the other four cultures of that microorganism. The antitoxin is protective and curative against infection with the spore and the vegetative stages of B. welchii in pigeons. The limits of the protective and curative action are now under investigation."

Glanders in Austria from 1911 to 1913, J. Schnürer (Wiener Tierärztl. Wchnschr., 1 (1914), No. 2, pp. 83-93; abs. in Vet. Rec., 28 (1916), No. 1438, pp. 339, 341).—An account of glanders control work in Austria during 1911, 1912, and 1913.

Neosalvarsan in the treatment of epizootic lymphangitis, E. Houdemeyer (Abs. in Vet. Rec., 29 (1917), No. 1496, pp. 372, 373).—Of the various methods of administering neosalvarson the author prefers intravenous injection since intramuscular injection is painful and subcutaneous injection should be discarded altogether on account of the persistent edemas which it produces. A dose of 1.5 gm. which is injected corresponds to 1 gm. of salvarsan. Of seven horses affected with epizootic lymphangitis that were treated with neosalvarsan six recovered after the first injection and the seventh after the second. "It is always advisable to combine surgical intervention with the administration of neosalvarsan by puncturing the abscesses and treating the wounds with antiseptics, as in this manner the progress of recovery is hastened." Attention is called to the importance of commencing treatment before the disease has become generalized.

Studies on the paratyphoid-enteritidis group.—I, II, C. KRUMWIEDE, JR., JOSEPHINE S. PRATT, and L. A. KOHN (Jour. Med. Research, 34 (1916), No. 3, pp. 355-358; 35 (1916), No. 1, pp. 55-62).—Two papers are given.

Xylose fermentation for the differentiation of B. paratyphosus "A" from other members of the paratyphoid-enteritidis group.—"In a series of cultures representing nearly all the pathogenic types of the paratyphoid-enteritidis group, a group of cultures, including all the types agglutinatively B. paratyphosus 'A', failed to ferment xylose. We suggest, if the study of further strains shows that this is a constant characteristic, that the xylose-negative types from man be considered the paratyphoid A group on cultural grounds. Within this cultural group are encountered strains, presumably pathogenic, which differ agglatinatively from the normal 'A' type."

Observations on the reaction in litmus milk as a method of biological differentiation.—" With the strains we have studied, the reaction in litmus milk of the different members of the paratyphoid-enteritidis group is a gradient one. Although most of the paratyphoid 'A' types produce alkali more slowly than the other members of the group, this difference is quantitative only, and intermediate degrees of reaction, both temporal and quantitative, largely destroy the differential value of the medium. The usually described qualitative reaction, therefore, has not been verified by our results. With milk containing Andrade indicator somewhat sharper differences are obtained with most of the strains, although the general quantitative character of the reaction is preserved. This is probably due to the greater delicacy of this indicator and coincident reduction of the color. Some strains, however, react irregularly on this medium, as on litmus milk, and show its lack of value as a qualitative method of differentiation."

Antitetanic serum in articular rheumatism, W. H. DALBYMPLE (Amer. Jour. Vet. Med., 12 (1917), No. 8, pp. 552, 553; Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 5, pp. 692-694).—The author, at the Louisiana Experiment Stations, reports the successful use of antitetanic serum in a case of articular rheumatism in a jack. Three doses of 500 units each were injected with apparent complete cure.

The vitality of the tubercle bacillus outside the body, M. B. SOPARKAR (Indian Jour. Med. Research, 4 (1917), No. 4, pp. 627-650).—The vitality of the tubercle bacillus was studied under varying external conditions.

The bacilli in the sputum when exposed to direct sunlight remained alive for six hours, but were killed after eight hours' exposure. On exposure to diffused daylight the organisms remained alive for six days, but were dead after exposure for eight days. Tubercle bacilli were kept alive and virulent for 309 days in sputum which was kept in darkness, even when it was completely desiccated. Living tubercle bacilli were isolated from decomposing sputum after 20 days, but not after 26 days. The bovine type was found to be more resistant to sunlight and diffused daylight than the human type. When exposed to electric light the bovine bacilli were found alive after 74 days, but were dead after 100 days. From three to four hours' exposure in direct sunlight and from three to four days in diffused daylight were found necessary for sputum to become sufficiently dried to be capable of being reduced to dust.

Incidence of bovine infection of tuberculosis in children, Ching Yik Wang (Edinb. Med. Jour., 18 (1917), pp. 178–196; abs. in Abs. Bact., 1 (1917), No. 3, pp. 266, 267).—Of 281 cases of tuberculosis examined in Edinburgh the bovine type of tubercle bacillus was isolated from 78.4 per cent of cases under 5 years of age, from 70.3 per cent of cases between the ages of 5 and 16 years, and from only 7.8 per cent of patients over 16 years. The bovine bacillus was found in 6 of 9 children who died of tuberculous meningitis and abdominal tuberculosis. The tuberculin test yielded positive results in 37.5 per cent of children fed on raw milk and in only 15.4 per cent of children fed on boiled milk.

The etiology of hog cholera.—Second report, F. PROESCHER and H. A. SEIL (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 5, pp. 609-624, figs. 13).—Continuing the study previously noted (E. S. R., 37, p. 382), data are reported which deal mainly with the blood changes, continued studies on the staining properties of the virus, microscopical changes in the organs, and the cultivation of the organism.

The blood changes in hog cholera were investigated with 12 pigs. Tabular data showing the absolute leucocyte count and the differential count, before and after incubation, are submitted. It is noted that the blood counts can not be regarded as conclusive on account of their incompleteness. The data obtained, however, show that in hog cholera there is at first a decrease in the absolute leucocyte count. In some of the animals a leucopenia was observed.

Shortly before death there may be a considerable increase in leucocytes. "In the majority of the cases the differential count showed a decided increase in the polynuclear neutrophils, with a decrease in the lymphocytes. The polynuclear eosinophils and basophils are greatly diminished in number or disappear entirely. Neutrophil myelocytes and plasma cells may appear shortly

before death. If the increase in leucocytes just before death is occasioned primarily by the hog-cholera virus or is due to a secondary infection with *Bacterium suipestifer* or *suisepticus* can not be determined." Two pigs showing a high ante-mortem leucocyte count were secondarily infected with *B. suipestifer*.

The staining method used for blood smears is briefly as follows: The airdried smears were stained in a methyl alcohol solution of eosin, methylene blue, and toluidin blue for three or four minutes, immersed for a few minutes in 96 per cent alcohol, washed in water, superficially dried, and then floated for 16 hours on a diluted Giemsa solution (1:10) alkalized with two drops of 1 per cent sodium carbonate or borax solution to 10 cc. The smears were then thoroughly washed in running water, air-dried, and mounted in cedar oil or in paraffin oil. This method is considered to be superior to that previously described.

Some observed histological changes in hog cholera which will be reported later in detail, together with the macroscopic changes, are noted.

For the cultivation of the virus both the blood and organs of pigs which succumbed to hog cholera were used. The blood was collected aseptically, defibrinated, centrifugalized, and the serum passed through a Berkefeld filter. The filtrate was tested aerobically and anaerobically for common bacterial contamination.

Only perfectly sterile serum was used for culture purposes. Unfiltered sterile carcinomatous ascites and sterile unfiltered horse serum were used as culture media. Either was placed in sterile test tubes to which a piece of fresh kidney or liver tissue from a guinea pig or rabbit was added, and covered with sterile paraffin oil. The tubes were then incubated for a week at 37° C. Tests were made to insure complete sterility.

To the sterile culture tubes filtered hog-cholera serum equal in amount to the culture medium was added by means of a sterile pipette. In one case blood taken directly from the heart which proved to be sterile was added directly to the culture medium. Cultures were made from the organs by taking pieces aseptically removed from the dead animal and immersing them in unfiltered sterile carcinomatous ascites or unfiltered sterile horse serum and then covering with sterile paraffin oil. The tubes which showed a high secondary infection were discarded. Those which were but slightly contaminated after incubation for a week were filtered through filter paper and then through a Berkefeld filter. The filtrates so obtained were used for subcultures, as previously described.

After two or three weeks the culture medium showed a slight opalescence which gradually disseminated through the liquid. In cultures made from filtered virus with the addition of a piece of fresh tissue a growth was observed in four weeks. In others, however, where the presence of the cocci was demonstrated microscopically, hardly any change in the culture medium could be noted. Several hundred cultures so prepared were examined microscopically. The data reported confirm the previous microscopic findings.

With the staining method described it was possible to demonstrate large masses of microorganisms attached to the red cells. These findings corroborate those of Meyer (E. S. R., 32, p. 475), who showed that hog-cholera virus adhered tenaciously to the red blood cells and that it was impossible to remove the virus by repeated washings with normal saline solution followed by centrifugalization.

It is indicated that "as soon as sufficiently distant subcultures are obtained, such that the transmission of the original virus is absolutely excluded, animal experiments will be made to furnish conclusive proof that this organism is the causative agent of hog cholera."

The virulence of hog-cholera blood at different periods during the disease, R. A. Whiting (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 4, pp. 477-493).— The results of a study at the Indiana Experiment Station covering a period of several years show that there is a gradual increase in the virulence of hog-cholera blood as the disease progresses from four to eight days following inoculation. Eight-day blood was found to be the most virulent.

It is noted that in the production of virus for serum production hogs may be killed at six days following inoculation, providing there is a corresponding high temperature and a manifestation of symptoms, especially weakness. Blood obtained on slaughter seven or eight days following inoculation was found to be more virulent than any of the blood obtained by tail bleedings.

See also a previous note by Craig (E. S. R., 34, p. 783).

Summary of observations on 1,470 hogs hyperimmune to hog cholera, H. C. H. Keenkamp (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 4, pp. 537-540).—Observations on 1,470 hogs used in the production of antihog-cholera serum at the Minnesota State serum plant, covering a period of approximately 37 months, are reported.

During the first half of the period of observation two methods of hyperimmunization were used, designated as "slow intravenous" and "intravenous." In the slow intravenous method an interval of from four to eight days between the first and the second injection of the necessary dose of virus to effect a condition of hyperimmunity was allowed. In the intravenous method the injection was done at one operation, the virus being injected into the posterior auricular vein under a pressure of from 3 to 6 lbs. per square inch. A smaller amount of virus is necessary in this method, and it is considered much more satisfactory than the slow intravenous method.

Serum therapy for trichinosis, B. Schwarz (Jour. Amer. Med. Assoc., 69 (1917), No. 11, pp. 884-886).—The report by Salzer that animals fed with infested meat later than 24 hours after the administration of serum from a convalescent animal prove to be immune, that infested meat mixed with immune serum does not produce trichinosis in animals to which it is fed, and that immune serum injected into animals suffering with the disease produces a curative effect led to the investigation here reported, which is summarized by the author as follows:

"Serum from animals convalescent from trichinosis when injected into other animals did not produce immunity to trichinosis in the latter. Trichinous meat mixed with serum from animals during the active or convalescent stage of the disease proved to be still capable of producing the disease. Animals once infected and harboring trichinæ in their muscles were not immune to further infection when fed trichinous meat. Serum from a trichinous animal had no observable ill effects on the larvæ freed from their cysts by artificial digestion. None of the results of the experiments appear to be in harmony with the assertions made by Salzer concerning the value of serum from convalescent animals as a prophylactic or curative agent in trichinosis."

Special equine therapy, M. R. Steffen (Chicago: Amer. Vet. Pub. Co., 1917, pp. 212).—This work gives special attention to diseases and conditions which are unnamed, atypical, or of infrequent occurrence, the discussions being entirely from the viewpoint of the general practitioner.

Trichomonasis of chicks: A new and highly fatal disease, J. Weinzirl (Jour. Bact., 2 (1917), No. 4, pp. 441-445, figs. 2).—Large losses of chicks on ranches in the Puget Sound region of Washington from disease led to the investigation here reported. It is concluded that a protozoan of the genus Tricho-

monas, to which the name *Trichomonas pullorum* is given, is the cause. The disease appears the second week after hatching, commonly about the tenth day, young chicks only being affected. Stock that is a month old proves resistant, and chronic cases that reach this age usually recover. Diarrhea is absent in the early stages but is present in the chronic stage. In the acute stage the chick may succumb in a day or two, and only the more vigorous birds enter the chronic stage. On the ranch where the investigation was first made 800 of 900 chicks hatched at one time from a thrifty stock of White Leghorns died within 10 days after hatching.

"Examination showed that a single species was present, frequently in overwhelming numbers; that it was not present in healthy stock, or in newly hatched chicks; that healthy chicks kept in cages with sick chicks developed the disease and showed the protozoan in the ceca; and finally that control chicks did not develop the disease when kept under identical conditions. We concluded, therefore, that this protozoan is the cause of the disease."

# RURAL ENGINEERING.

Evaporation from the surfaces of water and river-bed materials, R. B. SLEIGHT (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 5, pp. 209-262, pls. 6, flgs. 13).—Part 1 of this report deals with evaporation from water surfaces.

Experiments on the evaporation from circular land tanks of different diameters showed that "over the range of areas 0.785 sq. ft. to 113.1 sq. ft., or diameters 1 to 12 ft., the range in evaporation for the year is 76.18 to 49.16 in., and in percentage 154.9 to 100 per cent."

In experiments on the relation between evaporation from circular tanks and square tanks set 3 ft. in the ground, of equal exposed water surface, circular tanks with diameters of 3.39 ft. and 2 ft., and square tanks of dimensions 3 by 3 ft. and 1.77 by 1.77 ft. were used. "Based upon the totals, the evaporation from the larger square tank is 102.7 per cent of that from the circular one of the same area. That from the other square one is 103.5 per cent of that from the circular one of the same exposed area. Based upon mean weekly averages, these figures are 104.7 and 104.9. In the case of the 9 sq. ft. area the ratio, perimeter divided by area, is 0.15 greater in the case of the square tank than for the circular one. This has apparently caused an increase in evaporation of 2.7 per cent. For the tanks of 3.14 sq. ft. area there is a corresponding increase of 0.26 in the ratio and an increase of 3.5 per cent in evaporation."

Experiments on the variation of evaporation with the depth of the tank set in the ground showed that "during the months when the cooling effects of the night were not so great, the shallow tanks show the greater evaporation, but later, when the day temperatures and the heat storage of the shallow tanks are more than offset by the low night temperatures, the shallow tanks indicate a lesser evaporation. This difference in evaporation is not great, but for general use a tank not less than 2 ft. deep is recommended, since its contents will not become heated or cooled as quickly as those of the shallower tank. The difference between the results from the 6 ft. tank and the 3 ft. one is so slight that under all ordinary conditions there is no necessity for using a tank deeper than 3 ft."

Experiments on evaporation from flowing water showed that "for the first set of tanks evaporation from the flowing water was 107 per cent of that from the still water under exactly the same conditions. For the other set, a tank 25 ft. long, the evaporation from the flowing water was 108 per cent of that from still water.... There seems to be no definite relation between evaporation and velocity within the limits of the experiment."

Experiments on effects of temperature on evaporation and on the extension of the evaporation depths from land pans to larger open water surfaces under the same conditions by use of a floating pan are also reported, together with the results of meteorological observations taken in connection with evaporation investigations in general.

Part 2 of the report deals with evaporation from river-bed materials. "The final figures indicate that for the period of the sand-tank work the evaporation from the surface of the sand from the smaller tank, approximately 2 ft. in diameter, was about 7.5 per cent greater than from the larger tank. This figure does not check that found for the water tanks, the corresponding difference there being 3.5 per cent."

Other data of these experiments are graphically reported.

Use of power and rates for irrigation pumping, G. R. Kenny (Jour. Electricity, 38 (1917). No. 12, pp. 496, 497, fig. 1).—Data on the character of electric pumping plants in their relation to power rates, compiled from the practice of a hydroelectric company in California, are reported. Some data from typical districts on acreage irrigated and cost of power per acre are given in the following table:

Data on irrigated districts served.

	Alfalfa territory.	Citrus fruit territory.	Entire territory.
Acreage irrigated		9, 495 1, 470, 75	
Acres per horsepower.  Average acres per horsepower, all classes of crops	14.10	6.50	
Average costs per acre		\$6 to \$7	About \$4. 25

<sup>&</sup>quot;Practically all of the pumps in use are of the direct-connected centrifugal type. For the deep well pumping, the turbine and plunger types of well pumps are installed. The pumping motors on the system vary in size from 3 to 75 horsepower, only a very few being in excess of 15 horsepower, while the average at the end of 1916 was 10.4 horsepower."

The rates used, based on the maximum demand, are given in the following table:

Rates based on maximum demand.

Months continuous service.	Contract flat rates, per borsepower.	Meter rates, meter charge of 0.5 ct. per kwhour added to following demand charges.
3	\$17.50	\$10.40
1	21. 55 25. 15	12.50 14.30
6	28. 50	15.95
7	31.65	17, 45
8	34. 55	18. 85
9	37. 35	20. 10
10	40.00	21.30
11	42.55	22.40
12	45.00	23. 45

A survey of all gas engine pumping plants operating within one mile of the company's lines showed that "the gas engines were used where but little irrigation was required, when water was pumped from ditches, or where water was needed to supplement ditch irrigation after the ditches had gone dry. The engines are generally run for only a short period each year. About 1,200 en-

gines were visited and the conclusion reached, after the information obtained was examined, was that in the majority of cases the plants now pumping by gas engines could not be taken over for electric service to the advantage of either the consumer or the company. There are certain classes of power irrigation for which the gas engine, due to its low annual cost, if operated but little, may be used with considerable economy as compared with electric power."

The use of cement on national irrigation works, A. P. Davis (*Proc. Nat. Assoc. Cement Users*, 9 (1913), pp. 258-265, flgs. 7).—This is a statement of the use made by the U. S. Reclamation Service of cement in irrigation structures.

"Since its organization the Reclamation Service has used about 1,500,000 bbls. of Portland cement, representing about as many cubic yards of concrete. It has built about 7,000 miles of canals, 69 tunnels aggregating 111,000 ft., has built 18 storage dams and 25 diversion dams, about 2,000 concrete structures upon canals, and about 32,000 wooden structures. It has built altogether 2,908 bridges with an aggregate length of about 62,000 ft. It has built 436 offices and dwellings and about as many other buildings used for barns and storehouses."

Improvements proposed in the javellization of potable water for field service, Comte (Jour. Pharm. et Chim., 7. ser., 14 (1916), No. 9, pp. 261-263; abs. in Chem. Abs., 11 (1917), No. 6, p. 678).—A summary of service experience leads to the recommendation that a solution of 20 gm. of powdered potassium permanganate in 1 liter of hot water and 20 gm. of concentrated sulphuric acid be used for cleaning and deodorizing containing vessels.

It has been found that a uniform method of javellization is not applicable, owing to the variation in the organic impurities in the water and variations in the Javelle solution. It is pointed out that a definite amount of a given Javelle solution corresponds to a given water. This ratio is determined rapidly by placing 100 cc. of the water to be examined into each of five vessels and adding, respectively, 1, 2, 3, 4, and 5 drops of a 1:100 strength Javelle solution. After stirring and a wait of 20 minutes about 1 cc. of a potassium iodid starch reagent is added and again stirred. Several samples will then be blue. The sample of lowest concentration giving a blue color indicates the number of drops of undiluted Javelle solution necessary for the treatment of 10 liters of the water with the same dropping instrument. The starch reagent contains 1 gm. each of starch, potassium iodid, and crystalline sodium carbonate.

Experiments upon the purification of sewage and water at the Lawrence Experiment Station during the year 1915 (Ann. Rpt. Dept. Health Mass., 1 (1915), pp. 377-429, figs. 4).—This section of the report gives in detail the results of the water and sewage purification experiments at the station for the year 1915.

Annual report of the Baltimore County [Md.] roads engineer for the year ending December 31, 1916, W. G. Sucro (Ann. Rpt. Roads Engin. Baltimore Co. [Md.], 1916, pp. 87, pl. 1, figs. 17).—This is a report of work and expenditures on road construction, maintenance, and repair in Baltimore County, Md., for 1916.

Influence of grading on the value of fine aggregate used in Portland cement concrete road construction, F. H. Jackson, Jr. (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 5, pp. 263-274, figs. 10).—Experiments showing in a general way the effects of variations in the grading of fine aggregate on the resistance to wear of road concrete are reported.

It was found "that but few naturally occurring concrete sands are as coarse as those making the strongest mortars, according to these tests. Neither has the fact been overlooked that the best mortar, when combined with stone or

gravel without reference to its grading, will not necessarily produce the best concrete. A poorly graded, coarse aggregate will unquestionably require more mortar than will a well-graded one. Likewise, a coarse aggregate containing a large amount of small stone will allow the use of a somewhat finer sand than when the larger-sized stones predominate. . . . It might be considered practical to use a graded rather than a naturally occurring concrete sand in such important work as concrete road construction if, by so doing, the life of the pavement can be prolonged."

The effect of alkali on Portland cement, K. Steik (Wyoming Sta. Bul. 118 (1917), pp. 71-122, figs. 19).—Experiments are reported in which it was found that cement put into solutions of alkali salts set as well as in water. "In solutions of sodium sulphate CaSO.2H<sub>2</sub>O is formed. In solutions of magnesium sulphate CaSO.4, 2H<sub>2</sub>O, and Mg(OH)<sub>2</sub> are formed. In solutions of sodium chlorid a silicate is formed. The high percentage of sodium in this silicate is likely the reason for the increase of insoluble sodium in cement.

"Sodium chlorid in solution or its presence in solution with other alkali salts has its effect chiefly through a solvent action.

"Of the solutions tested, the 5 per cent sodium sulphate solution had the greatest disintegrating effects. Solutions containing chlorids, sulphates, and carbonates had the least effect. Mortars disintegrate faster than neat cement. The formation of compounds with molecular volumes larger than the molecular volume of calcium hydroxid is not the cause of disintegration of cement. The ultimate cause of the disintegration of cement by alkalies is due to the alkalies forming compounds with the elements of cement, which subsequently are removed from the cement by solution."

Spontaneous combustion as a cause of fires, A. R. LAMB (Iowa Sta. Circ. 36 (1917), pp. 4).—This circular deals with the spontaneous combustion of coal, drying oils, and especially hay, and briefly outlines means of preventing it.

"The self-heating of hay generally reaches a dangerous point about a month or six weeks after being mowed or stacked. Means of prevention must... be employed before this time. The most effective means is proper curing of the hay before storing it.... The hay should be carefully cured until the stalks are so dry that no moisture can be squeezed out by twisting a bunch in the hands. It must also be free from outside moisture, as dew or rain, when put into the barn.

"If the hay has unavoidably been put into the barn when somewhat moist it should be watched for signs of heating. The first evidence is shown in the morning, a day or two later, when the mow is covered with moisture condensed from the water vapor driven off in the heating. If the heating continues, craters or openings may be found near the center of the mow. If gases or pungent odors are driven off, the heating is great enough to be dangerous, and the hay should be removed at once."

Report of tractor ratings committee, R. Olney et al. (N. G. E. A. Bul., 2 (1917), No. 12, pp. 7-9).—The recommendations of the committee are "that the standard rating specifications for all tractors include belt horsepower, drawbar horsepower, drawbar pull in pounds, and engine and tractive speeds . . . but that for ordinary use in designating the different sizes or capacities of tractors, a standard rating be adopted such as is at present in general use. For example, tractors should be rated as 12-25, 10-20, 12-20, etc., in which the double number represents the drawbar and the belt horsepower, respectively.

"That the standard rating be on the following basis: (1) The drawbar horsepower rating must express the horsepower that the manufacturer will guarantee his tractor—when in good condition and properly operated at normal engine speed—to deliver at the drawbar continuously for two hours on a firm,

dry, level, earth road, with the tractor traveling at its rated plowing speed; (2) that the belt horsepower rating must express the horsepower that the manufacturer will guarantee the engine of his tractor—when in good condition and properly operated at normal speed—to deliver at the belt pulley continuously for two hours."

Farm buildings, with plans and descriptions, H. A. Shearer (Chicago: Frederick J. Drake & Co., 1917, pp. 256, figs. 148).—This book contains the following chapters: Economy of good farm buildings; two kinds of barn construction; horse and cow barn; enlarged dairy and horse barn; dairy barn for 28 cows; dairy barn for 30 cows; monitor roof dairy stable; new models for farm barns; miscellaneous farm buildings; hog houses for winter and summer; poultry, poultry houses, and poultry furniture; concrete on the farm; comfortable farm homes; and dictionary of building and architectural terms.

Considerable space is devoted to the chapter on comfortable farm homes, which includes plans and information regarding the construction of several types and sizes of farm dwelling. The section on the farm septic tank contains, among other matters, the following new information regarding sewage purification:

"A septic tank provides a scientific means of rendering sewage harmless.... Two kinds of bacteria work in a septic tank. Aerobic bacteria work in the first compartment and anaerobic bacteria work in the second compartment.... The size of the septic tank varies according to the amount of sewage to be disposed of. The capacity of the first box or compartment should be sufficient to hold two days' or three days' sewage before it runs over into the second compartment. The second compartment should be about the size of the first.... The final discharge from the septic tank is supposed to be inoffensive but it is generally recommended to discharge into 4-in. draintile so that the water can percolate away."

Silo building, W. D. Nicholls (Univ. Ky. Col. Agr., Ext. Div. Circ. 48 (1917), pp. 7).—This is a brief note on silo building in Kentucky.

Pit silos, T. P. METCALF and G. A. Scott (U. S. Dept. Agr., Farmers' Bul. 825 (1917), pp. 14, figs. 6).—This bulletin gives directions for constructing pit silos, indicating the proper size and best location, and describes the practices which have proved most satisfactory.

"Underground silos should be constructed only in soils that are firm and free from rocks, sand strata, and seeps, and where the water table is always below the bottom of the floor after they are dug. . . . The construction of pit silos is recommended only where a combination of soil and climatic conditions exists such as is found in the Great Plains region."

Reinforced concrete silos and small grain bins, E. S. Fowler (*Proc. Nat. Assoc. Cement Users*, 9 (1913), pp. 498-510, figs. 7).—This article reviews statistical data on concrete silo construction and gives information regarding small concrete grain bins and tanks.

# RURAL ECONOMICS.

Farm management [in Missouri], O. R. Johnson and R. M. Green (Missouri Sta. Bul. 147 (1917), pp. 38-40).—In these pages attention is called to the results of a survey to determine the cost of living in Missouri. It was found that the total cost of living on 191 farms in Saline County was \$555.80, of which the farm furnished \$239.80, while on 198 farms in Dade County the total cost was \$406.80, of which the farm furnished \$173.80. Data are also shown regarding animal units on Missouri farms, and the distribution of man and horse labor for various farm crops and live stock.

[Farm cost accounts at the Ontario agricultural experimental farm] (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 42 (1916), pp. 21-29).—These pages outline the method used to obtain the cost of producing crops, live stock, and live-stock products on the farm of the Ontario Agricultural College, under the various systems employed in its management. The accounts indicate, for the crops, the various items of expense, the total yield, yield per acre, and cost per unit; for live stock, they indicate the quantity of the various feeds used, the value of the products, and the profit for the year and per unit.

Plan for handling the farm-labor problem (U. S. Dept. Agr., Office Sec. Circ. 2 (1917), pp. 31).—The plan as outlined in this circular contemplates a State organization and separate county organizations, and a local organization for the distribution of agricultural laborers, and also provides for ascertaining the needs of every farm, not only as to number of additional laborers but as to the time when they are wanted. In the plan presented, each unit acts as a clearing house for its territory, reporting to the units higher up only surpluses or deficits.

Forms for use in the work are appended.

Agricultural labor question in Switzerland, IV (Pubs. Sec. Paysans Suisse, No. 54 (1917), pp. VII+194).—To restrict the necessity for manual labor in agriculture in Switzerland, the author considers measures relative to the (1) general organization of the country, such as the influence of area, land improvements, and buildings, (2) specific organization for cultivation purposes in the substitution of motors and the use of proper implements and machines, and (3) management of the work.

[Agricultural societies in Finland] (Landtbr. Styr. Meddel. [Finland], No. 114 (1914), pp. 91).—In this volume are contained reports regarding the work of various agricultural societies, indicating the membership, type of organization, functions performed, and accomplishments during the year 1914.

California resources and possibilities (Ann. Rpt. Cal. Develop. Bd., 27 (1916), pp. 64, pl. 1, figs. 5).—This report continues data previously noted (E. S. R., 35, p. 795).

New Hampshire farms.—Your opportunity (Concord, N. H.: Dept. Agr., 1916, 13. ed., pp. 42, pl. 1, figs. 30).—In this issue many advantages which the State offers to farmers are suggested.

[Agricultural resources of the State of New York], C. S. Wilson et al. (N. Y. State Food Sup. Com. Bul. 2 (1917), pp. 18).—This is a preliminary report of the agricultural resources of the State, ascertained through cooperation with the extension agents and school children. It indicates the amount of crops and live stock wanted and for sale by farmers, the amount of live stock on hand, amount of pasture, and the use expected to be made of the farm land.

An auto trip in New York State and what three men found about rural market conditions and farm trade (New York: Orange Juda Co., 1916, pp. 32, flgs. 28).—This report, based on interviews with farmers and country merchants, deals with rural market conditions and farm trade for the purpose of giving "advertisers first-hand, direct information regarding the attitude of rural merchants and farmers toward advertised goods, as well as a close view of the exact conditions, as reported by the dealers themselves, in the rural districts of New York State."

Corn is king in South Dakota (Pierre, S. D.: State [1917], pp. 32, figs. 17).— This bulletin is descriptive of the natural conditions, and the agricultural, mineral, and timber resources of the State, including opportunities for further development and settlement.

Statistics and resources of Utah.—Report of the State Bureau of Immigration, Labor, and Statistics, H. T. HAINES (Bien. Rpt. Bur. Immigr., Labor and

Statis. Utah, 5 (1915-1916), pp. 492, pls. 11, figs. 190).—This is a statistical and descriptive review of the various commercial, agricultural, mining, timber, and water-power resources of Utah, prepared to stimulate desirable immigration.

Joint report on the economic and agronomic conditions in the Cagayan Valley [Philippine Islands] in relation to tobacco, C. M. Hoskins et al. (Manila, P. I.: Govt., 1916, pp. 36).—The authors find that general economic conditions in the Philippine Islands are unsatisfactory, due (1) to the scarcity and high cost of money, (2) to the inadequate transportation facilities, and (3) to the unsatisfactory marketing methods. They recommend an immediate cadastral survey for the Cagayan Valley, a government loan to a suggested rural agricultural cooperative association, and the construction of the necessary highways.

A survey of agronomic conditions as to tobacco culture indicated room for improvement in the cultivation of pure strains through seed selection, better and more modern methods of culture, control of insect pests, and construction of proper curing sheds.

British industries after the war.—I, The land industry, W. EARNSHAW-Cooper (London: Cent. Committee Nat. Patriotic Organs., [1917], pp. 52).—This report discusses the possible development of agriculture in England and Wales after the war. It recommends the increasing of the productiveness of the soil to its maximum capacity, enlarging the number of live stock, making land settlement in England and Wales as satisfactory as in other countries, and devising means whereby the country can grow a larger proportion of its own food.

A national agricultural policy, J. H. C. Johnston (London: P. S. King & Son, Ltd., 1915, pp. 40, fig. 1).—The author presents a plan of land purchase for England, financially based on the principles of cooperative credit and occupying ownership, whereby the owner would receive part of the purchase price in cash and the balance in State guaranteed bonds, or the entire purchase price would be advanced to the farmer for a stipulated annuity.

Allotments and small holdings in Oxfordshire, A. W. Ashby (Oxford, England: The Clarendon Press, 1916, pp. VII+198).—This survey, which supplements recently published information by Orr (E. S. R., 37, p. 291), considers the history of allotments and small holdings, present conditions in reference to the demand for allotments, conditions of tenancy, methods of cultivation and economic effects, distribution of holdings, small holding colonies, county council holdings, and conditions as to employment, crop, and stock. The view is taken that allotments are made to cover a deficient labor wage and that the system of small holdings, while conducive to better agriculture, shows need for general improvement.

The economic resources of Russia, with special reference to British opportunities, A. Heyking (Jour. Roy. Statis. Soc., 80 (1917), No. 2, pp. 187-221).—With a discussion of the general economic resources, the author presents statistics concerning areas, production, and export of the wheat, rye, potato, oat, tobacco, and beet-sugar crops, and information is given showing the importance of live stock, bacon, and fruit. A discussion by members is appended.

Agricultural colonization of Tripoli (Agr. Colon. [Italy], 11 (1917), No. 2, pp. 183-187).—This report recommends the appointment of a special commission to study methods of placing soldiers on the land and the ascertaining of the regions most favorable for agricultural development.

[Land tenure and settlement; agriculture and live stock in New Zealand] (New Zeal. Off. Yearbook 1916, pp. 406-465, figs. 2).—These pages continue the data previously noted (E. S. R., 36, p. 690).

Prices and wages in India (Dept. Statis. India, Prices and Wages India, 32 (1917), pp. [2]+IV+VIII+266, pls. 3).—This volume continues data previously noted (E. S. R., 34, p. 195) by adding data for later years.

[Agricultural statistics of Japan] (Résumé Statis. Empire Japon, 31 (1917), pp. 227, pls. 4).—These pages give the area and production of the principal crops for 1915, with comparisons for earlier years, number of live stock for 1914, and area in forests and quantity of forest products harvested in 1915.

# AGRICULTURAL EDUCATION.

Secondary agricultural schools in Russia, W. S. Jesien (U. S. Bur. Ed. Bul. 4 (1917), pp. 22).—This bulletin deals with legislation for the maintenance of agricultural schools in Russia and the organization of secondary agricultural education, including admission requirements, statistics, sources of maintenance, courses of study, and the training of teachers. An account is also given of the organization and work of the Bessarabian School of Viticulture and Wine Making, at Kishenef.

The agricultural education act of 1904 places all private agricultural schools under the supervision of the ministry of agriculture and imperial domains, now known as the general office of land management and agriculture, and provides for the maintenance of schools controlled directly by this ministry and for a considerable part of the support of private schools. Government aid for agricultural schools controlled by the department of agriculture increased from \$964.838 in 1907 to \$2,000,440 in 1911.

The agricultural schools are divided into three classes—lower or primary, middle or secondary, and higher schools, the latter subject to regulations not included in this act. The secondary schools have for their object the furnishing to students of a practical agricultural education, based on scientific principles, in order to prepare them for agricultural work; the higher primary schools, preparation for practical farming; and the elementary schools, preparation mainly by practical instruction, of men informed and skilled in respect to farm work.

The secondary schools are stated to be admirably organized and managed and have a curriculum of wider scope than is necessary for purely practical instruction of peasant youths. Many of their graduates become managers of large estates, government officials, teachers, etc., while only a small part return to farming on a small scale. Almost all of the schools are boarding schools and nominal tuition fees are charged, but poorer children are aided by scholarships from government and private sources.

On January 1, 1910, there were 15 secondary agricultural schools, the oldest of which was founded in 1822 in Moscow. The number of instructors in these schools ranged from 7 to 26 per school, the number of students from 35 to 277, the annual expenditure from \$17.609 to \$54,550, and the value of school property from \$49,834 to \$598,400. The course of study extended over six years, the last year being devoted almost entirely to practical work. The general subjects taught have nearly the same scope as in the gymnasia. Horticulture is taught 2 hours weekly in the fourth year; agriculture 3 hours, zootechny 4 hours, farm economy 6 hours, survey of the farming industry 1 hour, agricultural technology 2 hours, agricultural machines and general mechanics 2 hours, and geodesy 2 hours weekly in the fifth and sixth years each; meteorology 1 hour weekly in the fifth year; and veterinary medicine and forestry 1 hour each a week in the sixth year. Courses for training teachers for primary agricultural schools have also been established at some of these schools.

Graduates of secondary agricultural schools may continue their education in higher agricultural schools where they are accepted without examination, while graduates of the viticultural school may continue their studies in the higher viticultural courses in Yalta, Crimea. The act of 1904 permits agricultural students to continue their studies after they have passed the age of conscription, which is 21 years, until the completion of the school program, but not after 24 years of age.

A bibliography of publications in the Russian language is included.

Twenty-third annual report of the inspector of State high schools, E. M. Phillips (Ann. Rpt. Insp. State High Schools Minn., 23 (1916), pp. 73, pls. 2).— This is a report on the progress in the work of the Minnesota State high schools in 1915–16. It includes statistical data on the location of State-aided departments of agriculture, the number of pupils, agricultural subjects in each year of the course of each school, number of short courses, salary of instructors, etc. Similar information is given with reference to State-aided departments of home training.

A description is given of a community school building erected at Wheaton, Minn., believed to be the first building of its kind in this country. It houses among other departments those of agriculture and home training, the county agricultural agent, and the Traverse County farm bureau.

The report indicates that of a total of 230 State high schools, 152 maintained departments of agriculture and received a total of \$142,992 State aid; 185 had departments of home training with a total of \$108,855 State aid. The total enrollment in the grades in agriculture was 5,013 and in home training 7,438, as compared with 3,992 in agriculture and 6,708 in home training in the previous year. The total enrollment in the high schools in agriculture was 4,643 and in home training 9,813, as compared with 4,527 in agriculture and 5,853 in home training in 1914–15.

Introduction of agriculture into public schools (Ann. Rpt. Dept. Agr. Prince Edward Island, 1916, pp. 46-51, fig. 1).—A brief account is given of the progress in the work of the rural science department of the Prince of Wales College in training teachers to give instruction in nature study and agriculture in the rural schools.

The education of the farmers by the regional agronomes, F. P. MAROTTA (Min. Agr. Nac. [Buenos Aires], Dir. Gen. Enseñanza e Invest. Agr. [Pub.] No. 62 (1916), pp. 5-19).—The author describes various phases of the work of the 20 regional agronomes in Argentina, including itinerant chairs, consultations and information, temporary courses, cooperative experiment fields, competitions and expositions, and rural cooperation. This extension service was created in 1908.

Report of the work of the school garden association in 1915 and 1916 (Ber. For. Skolehav. Virks. [Denmark], 1915-1916, pp. 47, figs. 22).—A brief summary is given of the school garden work in 1915 and 1916, followed by reports on the work of individual gardens in Denmark. Reports are also included on the instruction in school gardening given by the training schools or seminars for teachers at Växjø, Lund, and Gøteborg for men, and at Kalmar for women, and on the work of seven school gardens for children in Norway, including five in Christiania, and nine in Sweden.

Chronicle of the woman movement in German Switzerland in 1915–16, ELISA STRUB (Jahrb. Schweizerfrauen, 2 (1916), pp. 9–39).—The author reports on the progress in home economics, professional, social, and civic training of women, the activities of women's associations, and the professional and public life of women.

Report of the committee on teaching (Amer. Farm Management Assoc. Rpt., 6 (1915), pp. 79-82).—The committee confined its work to a study of graduate courses in farm management in different agricultural colleges. Answers to a questionnaire sent out indicate that graduate work is given in 13 institutions, 5 of which offer work leading to the doctor's degree. A list of problems for investigation and theses developed, leading to master's and doctor's degrees at different institutions, is included, as well as statistical data.

Farm management summer practice courses, R. L. Adams (Amer. Farm Management Assoc. Rpt., 6 (1915), pp. 40-50).—This is a description of the six-weeks' summer practice course, taken preferably between the sophomore and junior years, at the University of California, consisting of a tour of several of the distinctly agricultural sections of the State and detailed investigations in the various phases of agriculture. These trips have developed a decided farm-management aspect. Recommendations with reference to methods of carrying on the work are made, based on the results obtained from two years of these courses. The author states in conclusion that he feels so keenly the advantages which the students secure from this kind of work, that he is very reluctant for a man to substitute in any way whatever.

The scope and methods of instruction in rural sociology, J. M. GILLETTE (Pubs. Amer. Sociol. Soc., 11 (1916), pp. 163-182).—The author defines rural sociology and includes in its scope physical conditions, populations, economic production, communication, health, institutions and organizations, pathological social conditions, psychology of the rural social mind, problems of semirural communities, relation of country to city, and rural surveys. The methods of instruction are deemed identical with those used in other fields of social science.

The teaching of rural sociology, particularly in the land-grant colleges and universities, D. L. Sanderson (Pubs. Amer. Sociol. Soc., 11 (1916), pp. 181-208).—This article summarizes replies to a questionnaire as to the teaching of rural sociology sent out to representative universities and colleges of the country. The points covered include courses offered; relation to elementary sociology, political economy, rural economics, and education; definition; prerequisites, etc.

Preparation for editorial work on farm papers, N. A. Crawford (Kans. State Agr. Col. Bul., 1 (1917), No. 5, pp. 35).—A discussion based on replies by 146 managing editors of farm papers to a questionnaire as to the preparation desired of young men for agricultural journalism. In these replies, previous farm experience was given an average rating of 31.9, college training in agriculture 23.1, college training in journalism 13.2, experience on newspapers 17.1, and other qualifications 14.7 per cent.

Report of committee on suggestive course in agriculture for use in landgrant colleges of the South which give teacher training courses in agriculture, approved at New Orleans conference, April, 1916 (*High School Quart.* [Ga.], 5 (1917), No. 4, pp. 251-257).—An outline is given of the course approved at this conference as previously noted (E. S. R., 34, p. 799).

Practical agriculture in Texas schools through school, home, and community, J. D. Blackwell (Agr. and Mech. Col. Tex. Ext. Serv. Bul. 37 (1917), pp. 95, figs. 19).—This bulletin is intended as a guide to teachers undertaking definite projects in agriculture, and incidentally as a supplement to the numerous textbooks on elementary and high-school agriculture. It contains an explanation of home projects, home work, and credit, suggested outlines for reports on home projects, and outlines of subject matter for plant culture, general animal husbandry, dairy husbandry, poultry husbandry, fruit production, elementary soil study, vegetable and landscape gardening, crop production, and farm engineering and farm management. The outlines are planned on the basis

of a 1-unit course in general agriculture, which may, however, be enlarged upon and used in schools teaching two or more units. Each outline is followed by eight school exercises with directions for their performance, which may be given as a demonstration by the teacher or worked by groups or individuals, and which should be reported by the pupils in notebooks; also suggested field trips and home projects and home work, and lists of books and references. A monthly calendar for community projects is included.

Practical education: A home library of fourteen books in one, P. G. Holden, E. J. McFadden, and O. T. Beight (Chicago: The W. E. Richardson Co., Inc., 1917, pp. 521, figs. 89).—This text presents a plan for the cooperation of parent and teacher in organizing and conducting over 20 home school clubs. It includes directions for growing vegetables, fruit, and flowers in school-home gardens, raising poultry, pigs, and rabbits, keeping bees, cow testing and dairy work, stock judging, practical farm arithmetic and farm accounting, social center work, salesmanship and business efficiency, and outlines of work in sewing, cooking, canning, and home building, as well as suggestions to the teacher for correlating this work with other school subjects.

School and home gardens, T. I. Mais (Penn. State Col., School Bul. 5 [1917], pp. 28, figs. 22).—This bulletin contains a brief history of children's gardens and an enumeration of advantages that may be derived from children's gardens, an outline of a suggested classification of gardens based upon the purposes emphasized, suggestions with reference to gardens for schools in the country where probably for the most part the home garden should take the place of the school garden, selecting the site and crops, the size of the garden, and the preparation of the land, rules governing a garden contest for the high school, a home garden planting table, a form of records for a garden contest, plans of a model school garden prepared for the Panama-Pacific Exposition, and references to literature on gardening.

Home project at an agricultural school, C. H. LANE (High School Quart. [Ga.], 5 (1917), No. 4, pp. 265-267).—This is a brief statement of the home-project work required of students during the vacation between the second and third years of the 3-year courses in agriculture and horticulture for farm boys offered at the college of agriculture of the Ohio State University. These courses are complete in themselves and do not offer preparation for any of the four-year curricula, nor are they accredited toward a degree on any of these curricula.

Productive plant husbandry, K. C. Davis (Philadelphia and London: J. B. Lippincott Co., 1917, pp. XVI+462, pl. 1, figs. 312).—This textbook for high schools treats the subjects of plant propagation and breeding, soils, field crops, gardening, fruit growing, forestry, insects, plant diseases, and farm management. Field and laboratory exercises, including suggestions for home projects, and references to literature for supplementary reading are given at the close of each chapter. One school year is allowed for the completion of the studies and exercises, and a preliminary study of botany is not considered essential to the understanding of the lessons.

Agricultural botany, W. Whitney (School Sci. and Math., 17 (1917), No. 6, pp. 488-494).—The author considers briefly the principles which should underlie the construction of a course in botany, and outlines whole year and half-year suggestive courses in agricultural botany in which the order of topics is determined so far as practicable by the season.

Feed manual and notebook, F. W. Woll (Philadelphia and London: J. B. Lippincott Co., 1917, pp. 137).—This manual, which has been prepared for students in agricultural schools and colleges, consists of exercises (1) relating to the value of the common feeding stuffs used in this country, their chemical composition and digestibility, methods of preparation, examination for purity,

relative feeding /alues, etc.; and (2) illustrating calculations of rations for farm animals, the rights and wrong uses of the various feeds for feeding horses, cattle, sheep, swine, and poultry, and general problems connected with the feeding of farm stock. Digestion coefficients of common feeding stuffs, in percentages, and a brief list of suggested apparatus with prices are included.

Proceedings of the twenty-first annual meeting of the American Association of Farmers' Institute Workers, edited by L. R. TAFT (Proc. Amer. Assoc. Farmers' Inst. Workers, 21 (1916), pp. 139, figs. 2).—This is a detailed report of the proceedings of the meeting held at Washington, D. C., on November 13-15, 1916. It includes the reports of committees on institute organization, institute lecturers, cooperation of farmers' institutes with other educational agencies, movable schools of agriculture, young people's institutes, resolutions, etc., and the following papers: President's address, by F. S. Cooley; farmers' institute work in Wisconsin, Delaware, Michigan, Texas, Pennsylvania, and Iowa, by E. L. Luther, W. Webb, L. R. Taft, J. W. Neill, C. E. Carothers, and Catherine J. MacKay, respectively; extension work in Oregon, by Anna M. Turley; The Work of the U. S. Department of Agriculture, by C. Vrooman; The Extent and Possibilities of Cooperative Marketing, by C. E. Bassett; The Relation of the Smith-Lever Funds to Farmers' Institutes, by A. C. True; The Present Relation of Farmers' Institutes and Extension Schools, by D. J. Crosby; A Balanced Ration for a Community, by J. C. Ketcham; The Humus Content of the Soil, by H. J. Wheeler; Nebraska Junior Institutes in Agriculture and Home Economics; The School Lunch Basket and Its Preparation, by Mrs. D. H. Stockman; A Home Demonstration Project, by Anna M. Turley; Extension and Farmers' Institute Work in Home Economics, by Belle M. Hoover; Women's Institute Work in Ontario, by G. A. Putnam; Essentials in Home Economics Teaching, by Mrs. I. L. Harrington; Statistics of Farmers' Institutes in the United States, 1915-16, by J. M. Stedman; and special notes of the work in various States and notes on farmers' institute work in Canada.

# MISCELLANEOUS.

Report of the Guam Agricultural Experiment Station, 1916 (Guam Sta. Rpt. 1916, pp. 58, pls. 10, figs. 5).—This contains reports of the agronomist in charge, the foreman of the Cotot stock farm, and the animal husbandman and veterinarian. The experimental work recorded is for the nost part abstracted elsewhere in this issue.

Work and progress of the agricultural experiment station for the year ended June 30, 1916 (Missouri Sta. Bul. 147 (1917), pp. 64, figs. 10).—This contains the organization list, a report of the director on the work and publications of the station, and a financial statement for the Federal funds for the fiscal year ended June 30, 1916. The experimental work reported and not previously noted is for the most part abstracted elsewhere in this issue.

# NOTES.

Alabama Canebrake Station.—J. M. Burgess, associate professor of dairying at Clemson College, has been appointed director beginning about December 1.

California University.—Several special short courses are being offered at Davis and Riverside on gas tractors, and at Davis to practical cheese makers on improved methods in cheese making.

New York State Station.—James E. Mensching, of the Pennsylvania Institute of Animal Nutrition, has been appointed associate agronomist to succeed R. C. Collison, promoted to agronomist and given leave of absence for post-graduate work at Columbia University for the year.

Ohio State University and Station.—Vernon H. Davis, professor of horticulture, has resigned to become director of the new State bureau of markets.

At the station Thomas L. Guyton and Jacob R. Stear have been appointed assistants in entomology. J. T. Parsons has been appointed assistant in soils.

Oklahoma College and Station.—W. L. Carlyle has resigned as dean and director to engage in business in Calgary, Alberta. President J. W. Cantwell has been designated acting director of the station.

Pennsylvania Institute of Animal Nutrition.—A frame building 25 by 45 feet is being erected for the use of the Institute. It will contain stalls and other appliances for the digestion and metabolism experiments carried on in connection with the investigations with the respiration calorimeter and will also afford storage for the feeding stuffs used.

Mark C. Lewis, a 1917 graduate of the college, has been appointed assistant in animal nutrition, vice William H. Matthews, resigned to enter the military service.

Tennessee Station.—The selection by the State commission of a site of 680 acres near Columbia in Maury County for the Middle Tennessee substation has been accepted by the county court of that county, which has appropriated approximately \$100.000 for the purchase of the property. Another fund of \$100,000 for buildings and a maintenance fund is available under the State legislation previously referred to (E. S. R., 37, p. 198).

Work has been begun on the new dairy barn on the Cherokee Farm of the main station. This is to cost \$6.500, including two siles and accommodations for about 30 cows.

Utah Station.—The dairy barn has been renovated and additional equipment installed, including a new milk room. The poultry department has recently completed two semimonitor and two shed-roof poultry houses, which will accommodate about 400 birds and cost approximately \$700. The department of meteorology has installed a complete set of meteorological instruments.

H. J. Maughan has resigned as assistant agronomist to engage in ranching in Wyoming, and A. O. Larson, as assistant entomologist, to accept a position in the high school at Manhattan, Mont.

Vermont University and Station.—H. E. Bartram, assistant plant pathologist in the station, resigned October 31 to begin demonstration work in plant pathology in connection with the extension service.

Washington College and Station.—F. J. Sievers, superintendent of the county school of agriculture at Wauwatosa, Wis., has been appointed professor of soils and soil physicist to succeed C. C. Thom. A. B. Nystrom, dairy husbandman, has resigned to accept an appointment as county agriculturist of Lewis County, effective October 1.

American Association for the Advancement of Agricultural Teaching.—The eighth annual meeting of this association was held in Washington, D. C., November 13, 1917. Special prominence was given to problems affecting secondary education, including developments under the Federal Vocational Education Aid Act.

W. H. French, of Michigan, president of the association, traced the development of secondary school agriculture in this country from 1888 to the present, calling attention to the prominence now given the subject through the passage of the Federal Vocational Aid Act. J. P. Monroe, of the Federal Board for Vocational Education, discussed the act in operation. He laid emphasis on the fact that this act provides for normal education for normal persons. It is not an inferior kind of education but aims to make broad and intelligent citizens. He also described the present Federal organization, and outlined some of its policies. L. S. Hawkins, assistant director of agricultural education for the board, under the subject What Constitutes Proper State Supervision of Home Projects, showed how the supervision should stimulate progress and encourage the teachers rather than merely standardize and contribute a check as to formal requirements.

F. B. Jenks, of the University of Vermont, showed how practical and valuable extension service might be the logical outgrowth of the high school work in agriculture and how this might cooperate with the work of the county agent within the territory of the school. Numerous examples of this service as rendered by high schools in Vermont were cited.

In a paper on Minimum Laboratory Equipment for Agriculture in Public Secondary Schools, by J. A. James, supervisor of secondary agriculture of Wisconsin, emphasis was laid on the necessity for useful apparatus which in many cases might be found and used at the home farms. The list of absolutely essential apparatus was very brief and for the most part comprised material useful in farm operations.

The relations of the association to the National Society for the Promotion of Industrial Education were discussed, and resolutions adopted declaring that the association should continue, but take steps looking toward the proper recognition and representation of agriculture in the society, and possibly to an amalgamation of these organizations. The incoming president, together with W. R. Hart of Massachusetts, and Z. M. Smith of Indiana, were appointed to represent the association in this matter.

The standing committee on the cooperative use of equipment and illustrative material presented a report by H. P. Barrows on Illustrative Material Through the States Relations Service. The committees on essential laboratory equipment for teaching agriculture in secondary schools and the relation of general science to agricultural instruction reported progress and were continued with the same personnel for another year, but a resolution was adopted substituting annual committees for standing committees.

The officers elected for the ensuing year were as follows: President, G. A. Works, Cornell University; vice president, W. G. Hummel, field agent of the Federal Board for Vocational Education; secretary-treasurer, F. E. Heald, States Relations Service; and additional members of the executive committee, L. S. Hawkins, Federal Board for Vocational Education; G. M. Wilson, Iowa State College; and Dean Alfred Vivian, Ohio State University.

American Society of Agronomy.—The tenth annual meeting of this society was held in Washington, D. C., November 12 and 13.

The presidential address was given by W. M. Jardine at a joint session held with the Society for the Promotion of Agricultural Science. Dean Jardine took for his subject The Agronomist of the Future, outlining the opportunities for service and the obligations imposed upon the trained agronomist with respect to the present emergency. He especially emphasized the necessity of gaining the confidence of the farmer by offering him ideas which are practical and workable as well as theoretically correct, and likened the agronomist to the "middleman" standing between the investigator in pure science and the farmer. Me maintained further that the primary duty of an agricultural college in granting the B. S. degree was to train agricultural teachers and farmers, not to turn out full-fledged scientific investigators. In concluding he urged that the agronomist be untiring in his study of the fundamentals and that the society encourage its members to pursue research studies.

Other papers presented before the society included the following: Mineral Food Requirements of the Wheat Plant at Different Stages in Its Development, by A. G. McCall; Effect of Sodium Nitrate Applied at Different Stages on the Yield, Composition, and Quality of Wheat, by J. Davidson and J. A. LeClerc; Some Facts Regarding the Soft or Flour Corns, by H. H. Biggar; Drainage Tanks for Soil Investigations—Some Preliminary Studies, by C. A. Mooers; Organizing Crop Production on the Basis of the Distribution of the Natural Vegetation, by A. E. Waller; Realtion of Weed Growth to Nitric Nitrogen Accumulation in the Soil, by L. E. Call and M. G. Sewell; Wheat Breeding Ideals, by H. Snyder; Red Rock Wheat and Rosen Rye, by F. A. Spragg; Calcium in Its Relation to Plant Nutrition, by R. H. True; The Triangle System for Fertilizer Experiments (with some remarks on the potash hunger of potatoes), by O. Schreiner and J. J. Skinner; Some Tests of an "All-Crops" Soil Inoculum, by P. Emerson; Corn and Wheat Soils in the United States, by C. F. Marbut; Methods Used in Cereal Investigations at the Cornell Station, by H. H. Love and W. T. Craig; The Significance of the Sulphur in Sulphate of Ammonia Applied to Certain Soils, by C. B. Lipman; and Aluminum as a Factor Influencing the Effect of Acid Soils on Different Crops, by B. L. Hartwell and F. R. Pember.

One entire session was devoted to varietal classification and nomenclature. A report of the committee upon varietal nomenclature embracing six years' work was read and discussed. This report is to be published in full in the Journal of the American Society of Agronomy. It included a "Code of Nomenclature," and a motion was adopted that the society appoint a committee to "act in cooperation with the American seed trade and any other agencies to secure uniformity in rules and practices of varietal nomenclature and registration." In connection with the presentation of the report, C. R. Ball discussed The Classification of Western Wheat Varieties, exhibiting mounted specimens to illustrate the scheme of classification employed, and gave a paper on Naming American Wheat Varieties, which outlined the use of the proposed Code of Nomenclature as applied to wheat. Mr. Ball emphasized the immediate necessity for a systematic naming of varieties, to be followed later by a scheme of classification.

Summarized reports were submitted by the committees on the standardization of field experiments and agronomic terminology. Brief reports were also submitted from local sections in Iowa, Kansas, Cornell, Ohio, South Dakota, New England, and Washington, D. C.

The following officers were elected for the ensuing year: President, T. L. Lyon; vice presidents, A. G. McCall and C. B. Lipman; and secretary-treasurer, P. V. Gardon.

Potato Association of America.—The fourth annual meeting of this association was held in Washington, D. C., November 9 and 10, 1917.

The program included addresses by Assistant Secretary Vrooman of the U. S. Department of Agriculture, Hon. H. C. Hoover, W. T. Macoun, C. A. Zavitz, and W. S. Blair, and papers on the following subjects: Feeding Value of Raw, Cooked, Silaged, and Pressed Dried Potatoes for Hogs, by F. G. Ashbrook; Feeding Value of Silaged and Pressed Dried Potatoes for Dairy Animals, by T. E. Woodward; The Farm Manufacture of Potato Starch, by H. C. Gore; The Preparation of Potato Silage, by L. A. Round; The Dehydration of Potatoes, by L. D. Sweet; Potato Utilization Work of the Bureau of Chemistry, by C. L. Alsberg; Fertilizer Studies on Potash Hunger of the Potato and Other Field Crops, by O. Schreiner; The Dietary Value of the Potato, by C. F. Langworthy; The Potato Situation and the Department's Work on Potatoes, by L. C. Corbett; Distribution of the Potato Crop, by E. P. Miller; Car Movement of Potatoes, by H. Elliott; Potato Growing and the Present Fertilizer Situation, by H. G. Bell; and The Production of High-Grade Seed Potatoes, by D. Dean.

Committee reports were also submitted upon seed improvement and certification, research, varietal nomenclature and testing, market standards and marketing, utilization of surplus stock and culls, transportation, potato contests and exhibitions, crop forecasting, publications, and education.

Officers were elected for the ensuing year, as follows: President, L. D. Sweet; vice president, W. T. Macoun; secretary-treasurer, W. Stuart; and members at large of the executive committee, H. G. Bell and H. E. Horton.

Miscellaneous.—The report of the committee of the Privy Council for Scientific and Industrial Research of Great Britain for 1916-17 states that substantial progress has been made for establishing a national research association for cotton. The committee has offered a grant of money to the Imperial Commissioner of Agriculture in the British West Indies, and it is hoped that in due course the new association may take over this work.

The food production department of Great Britain has established a seed-testing station in London. H. B. Renwich has been appointed director of feeding stuffs at the ministry of foods to organize the supply and distribution of feeding stuffs, particularly oil meal.

Plans are being devised in Great Britain for holding short training courses for soldiers who are available for agricultural work. Particular attention is to be given to the handling of farm machinery, especially tractors and plows.

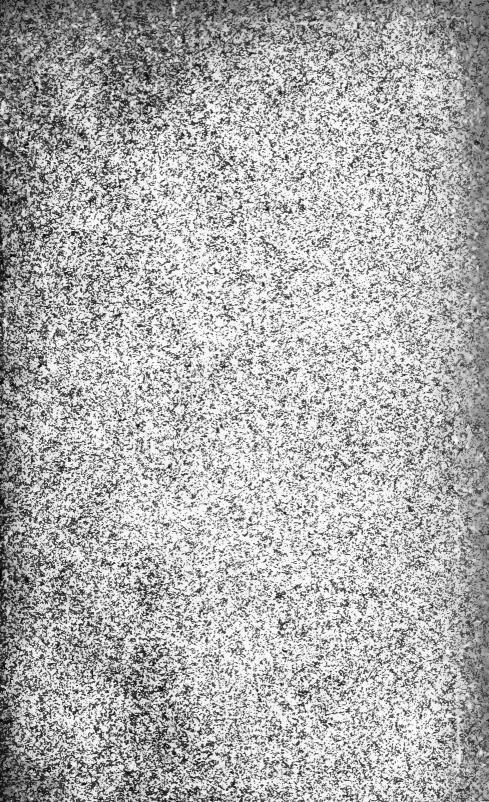

A national institute is to be established in Italy to investigate the relations between malaria and agriculture, the cause of the unhealthfulness of malarial districts, and the organization of a campaign against these causes.

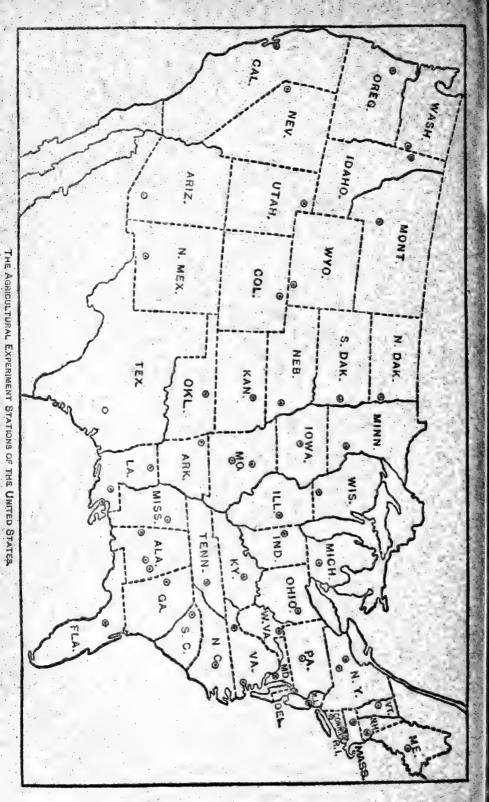

A chair of the pedagogy of agriculture has been established at the University of South Carolina. V. E. Rector, principal of the Antioch Industrial School, has been appointed to the position.

Sulphuring Concord grapes to prevent mildew, Gladwin and Reddick	843
The generation of aldehydes by Fusarium cubense, Lathrop	843 843
Sourcet of lamon in California Smith	843
Sour rot of lemon in California, Smith.  Two new camphor diseases in Texas, Taubenhaus.	843
Diseases of cinchona, Rant.  A disease of pecan catkins, Higgins.	844
A disease of pecan catkins, Higgins	844
Phytophthora on Vinca rosea, Dastur	844
Notes on some species of Coleosporium, Hedgcock and Hunt	844
The acial stage of Coleosporium elephantopodis, Hedgcock and Long	844
An alternate form for Coleosporium helianthi, Hedgcock and Hunt	844
Some new hosts for Coleosporium inconspicuum, Hedgcock and Hunt.	844
The Peridermium belonging to Coleosporium ipomæx, Hedgoock and Hunt	845
Some new hosts for Coleosporium solidaginis, Hedgeock and Hunt.	845 845
A Peridermium belonging to Coleosporium terebinthinacea, Hedgoock and Hunt.	845
Notes on Cronartium comptonix, III, Spaulding.  Does Cronartium ribicola winter on the currant? McCubbin	845
Evidence of the overwintering of Cronartium ribicola, Spaulding	846
The pine blister, Paul	846
The pine blister, Paul	846
Some new or little known hosts for wood-destroying fungi, Rhoads	846
ECONOMIC ZOOLOGY-ENTOMOLOGY.	
	0.40
A new subspecies of meadow mouse from Wyoming, Bailey	846
Diagnosis of a new laniine family of Passeriformes, Oberholser	846
Description of a new Sialia from Mexico, Oberholser	846 846
Friends of our forests, Henshaw.  Report of the entomologist of Arizona for 1916, Morrill.	846
Annual report of the State entomologist for 1915, Worsham	847
Report of the division of entomology, 1916, Ehrhorn	847
Report of the economic biologist, Bodkin	847
Observations on some insects attacking rice, Supino	847
Wild vegetation as a source of curley-top infection, Boncquet and Stahl	847
Meadow and pasture insects.—Practical methods of control, Osborn	847
Insects that factor in the grading of apples, Parrott	847
Spraying for insects affecting orchards in Nova Scotia, Sanders and Brittain	848
Insects injuring stored food products in Connecticut, Britton.  The carriage of disease by insects, Howard	848 848
Key for identification of parasites in human feces, Martin and McKittrick	848
Volatility of organic compounds as an index of toxicity to insects, Moore	848
Lead arsenates, stone fruits, and the weather, Gray	848
Locust control in various countries, Trinchieri	848
Report on control work with the locust in Uruguay, Sundberg et al	849
Experiments in locust control in Argentina, Kraus	849
Summary of locust work for the third quarter, 1916, South	849
A new Sericothrips from Africa, Hood  A new species of Corythuca from the Northwest, Gibson.	849
The terrete and leaved regulide. Feeig	849
The tomato and laurel psyllids, Essig.  The pink and green potato plant louse.—A new pest for Ohio, Houser	849 849
Some sensory structures in the Aphididæ, Baker	850
Eastern aphids, new or little known, I, Patch	850
. , ,	

	Page.
Eastern aphids, new or little known, II, Baker	850
The Aphididæ of Java, van der Goot	850 850
[Studies of pediculi]	850
The louse problem, Bacot.  Isolation of Bacillus typhi-exanthematici from body louse, Olitsky et al	850
The lesser cornstalk borer, Luginbill and Ainslie	851
The lesser cornstalk borer, Luginbill and Ainslie.  Control of the grape-berry moth in the Erie-Chautaqua grape belt, Isely	852
Pathogenicity of so-called Sotto bacillus of silkworms, Aoki and Chigasaki	853
The atoxogen type of Bacillus sotto, Aoki and Chigasaki	853 853
Distance of flight of Anopheles quadrimaculatus, Le Prince and Griffitts  Notes on the early stages of Chrysops, Marchand	853
Sarcophage hamorrhoidalis larvæ as parasites of human intestine, Haseman	853
Fly investigation reports, I-III, Saunders	853
Flies and typhoid, Nicoll	854
Relation of Pegomyia fusciceps to certain crops in Louisiana, Tucker	854
A buprestid household insect (Chrysophana placida), Burke	854 854
The life history of Diapus furtivus, Beeson  The weather and honey production, Kenoyer	854
Seventh report of State inspector of apiaries, 1916, Gates	855
The domestication of the Indian honeybee, Newton	855
Life history and habits of <i>Polistes metricus</i> , Pellett	855
Habits of western wheat stem sawfly in Manitoba and Saskatchewan, Criddle	855
An American species of the hymenopterous genus Wesmælia of Foerster, Myers	855
Report on a collection of Hymenoptera made by W. M. Giffard, Rohwer	855 855
Australian Hymenoptera Chalcidoidea, Girault.  Parasitism of Mediterranean fruit fly during 1916, Pemberton and Willard	856
Notes on the construction of the cocoon of Praon, Ainslie	856
An egg parasite of the sumac flea-beetle, Crosby and Leonard	856
An aphis parasite feeding at puncture holes made by the ovipositor, Rockwood.	856
Megastigmus aculeatus introduced into New Jersey from Japan, Weiss	856
The embryonic development of Trichogramma evanescens, Gatenby Life history and habits of the spinose ear tick, Ornithodoros megnini, Herms	856 856
Tarsonemus pallidus, a pest of geraniums, Garman	856
The cyclamen mite, Moznette	857
A synopsis of the genera of beetle mites, Ewing	858
On the nymph and prosopon of Leptotrombidium akamushi n. sp., Nagayo et al.	858
Is Trombidium holosericeum the parent of Leptus autumnalis? Nagavo et al	859
Notes on the parasitic acari, Hirst.  The chicken mite: Its life history and habits, Wood.	859 859
New mites, mostly economic, Banks	860
Tren mirror, mostly consider, Danks	
FOODS-HUMAN NUTRITION.

## RECENT WORK IN AGRICULTURAL SCIENCE.

## AGRICULTURAL CHEMISTRY-AGROTECHNY.

Principles of agricultural chemistry, G. S. Frans (Easton, Pa.: The Chemical Publishing Co., 1917, 2. ed., pp. 501, figs. 94).—This is the second edition of the work previously noted (E. S. R., 30, p. 10). A number of additions and changes have been made which include some of the recent advances in the subject, especially with reference to soil organisms, nutritive value of protein, and productive value of feeds.

An introduction to the chemistry of plant products, P. Haas and T. G. Hill (London and New York: Longmans, Green & Co., 1917, 2. ed., pp. XII+411, figs 5).—This is the second edition of the work previously noted (E. S. R., 31, p. 803).

Due to the great advances made in the chemistry of plant pigments since the issue of the first edition, this section has been entirely rewritten. A few other minor additions and changes have been made and further references to the literature added.

The occurrence of mannite in silage and its possible utilization in the manufacture of explosives, A. W. Dox and G. P. Plaisance (Science, n. ser., 46 (1917), No. 1182, pp. 192, 193).—Analytical data obtained by the authors at the Iowa Experiment Station in the course of investigations on the fermentation processes that occur immediately after the ensiling of corn and the chemical products resulting therefrom show the presence of considerable amounts of mannite in various kinds of silage. The highest percentages of mannite were found in sunflower silage, cane silage, and an experimental corn silage to which sucrose had been added. It is indicated that the mother substance of the mannite is apparently sucrose or, more specifically, its fructose moiety. The presence of the mannite was shown not to be a local phenomenon, since the samples of silage examined were obtained from several different States. Corn and cowpea silage, sweet clover silage, and ensiled corn stover plus glucose contained no mannite.

A method of preparing quantities of mannite without special regard to quantitative yields and the use of its nitration product in the manufacture of explosives are noted.

See also a previous note by Manns (E. S. R., 1, p. 200).

The occurrence and significance of mannitol in silage, A. W. Dox and G. P. PLAISANCE (Jour. Amer. Chem. Soc., 39 (1917), No. 9, pp. 2078-2087).—This is a more detailed account of the material noted above.

The occurrence of 1-leucin in sweet clover silage, G. P. Plaisance (Jour. Amer. Chem. Soc., 39 (1917), No. 9, pp. 2087, 2088).—In the examination of sweet clover silage for mannite by the author, at the Iowa Experiment Station, no evidence of the substance was found. Instead a white substance crystallized in little round masses, which after recrystallization from dilute alcohol was identified as 1-leucin. In the samples of sweet clover silage examined leucin was recovered in amounts ranging from 0.4 to 1 per cent of the dry material.

The action of acids on the rotatory power of sucrose and invert sugar in the presence of soluble salts, E. Saillard (Compt. Rend. Acad. Sci. [Paris], 165 (1917), No. 3, pp. 116-118).—Data obtained in connection with work on beet molasses show that sulphurous acid and acetic acid do not change the rotatory power of sucrose in the presence of sodium chlorid. These acids do, however, diminish the rotation of invert sugar in the presence of sodium chlorid, with or without the addition of hydrochloric acid. Hydrochloric acid increases the polarization of a solution of invert sugar in the presence of salt. The solutions of invert sugar containing salt and sulphurous acid yield an unstable polarization because of the easy loss of part of the dissolved gas. Carbon dioxid does not influence the rotation of solutions of sucrose or invert sugar, undoubtedly because of its slight solubility.

Glycolytic properties of muscular tissue, R. Hoagland and C. M. Mansfield (Jour. Biol. Chem., \$1 (1917), No. 3, pp. 501-517).

The function of muscular tissue in urea formation, R. Hoagland and C. M. Mansfield (Jour. Biol. Chem., 31 (1917), No. 3, pp. 487-499).

Determination of carbonates in limestone and other materials, J. F. BARKER (Jour. Indus. and Engin. Chem., 9 (1917), No. 8, pp. 786, 787, fig. 1).—Essentially noted from another source (E. S. R., 37, p. 616.)

Insoluble phosphoric acid in organic base goods, E. O. Thomas (Jour. Indus. and Engin. Chem., 9 (1917), No. 9, p: 865).—Analytical data are submitted from which it is concluded that in the determination of citrate-insoluble phosphoric acid the official method gives the true value of acid phosphate, but that in the analysis of materials of the character of acidulated garbage tankage some modification should be used.

The decomposition of dilead arsenate by water, C. C. McDonnell and J. J. T. Graham (Jour. Amer. Chem. Soc., 39 (1917), No. 9, pp. 1912-1918, figs. 2).—Experimental data obtained in the study show that dilead arsenate is decomposed by water. The reaction is represented by the the equation

$$5PbHAsO_4 + HOH \Longrightarrow Pb_4(PbOH)(AsO_4)_3 + 2H_3AsO_4$$
.

The reaction proceeds with the liberation of arsenic acid and the solution of a very small quantity of lead. Equilibrium is reached while the concentration of arsenic acid is very low. If the water is constantly changed, however, the reaction proceeds until the residue is converted to a definite basic lead arsenate (hydroxy mimetite,  $Pb_4(PbOH)$  (AsO<sub>4</sub>)<sub>4</sub>·H<sub>2</sub>O.

Allen's commercial organic analysis, edited by W. A. Davis (Philadelphia: P. Blakiston's Son & Co., 1917, 4. ed., rev., vol. 9, pp. XVIII+836, figs. 18).— This is a supplementary volume to the work previously noted (E. S. R., 30, p. 309) which brings the text, especially that of the earlier volumes, up to date. The chapters included are alcohols; malt and brewing materials; wines and spirits; yeast; neutral alcoholic derivatives; sugars; starch and its isomerids; paper and paper-making materials; aliphatic acids; fixed oils, fats, and waxes; special characters and modes of examining fats, oils, and waxes; butter fat; lard; linseed oil; soaps; glycerol; cholesterol; wool, grease, and cloth oils; hydrocarbons; bitumens; naphthalene and its derivatives; phenols; aromatic acids; resins; india rubber, rubber substitutes, and gutta-percha; essential

oils; special characteristics of essential oils; tannins; analysis of leather; analysis of coloring materials; coloring matters of natural origin; coloring matters in foods; printing inks; inks; amins and ammonium bases; anilin and its allies; the naphtylamins and their allies; the vegetable alkaloids; volatile alkaloids; estimation of nicotin; aconite alkaloids; atropin and its allies; cocaine; opium alkaloids; strychnos alkaloids; cinchona alkaloids; berberin and its associates; caffein, tea, and coffee; other vegetable alkaloids; glucosids; nonglucosidal bitter principles; animal bases; animal acids; lactic acid; cyanogen and its derivatives; enzyms; proteins; vegetable proteins—flour; proteins of milk; milk products; albuminoids; meat and meat products; fibroids; and an appendix.

A complete author and subject index of the entire work is included in the volume.

New apparatus for colorimetry, E. Moreau (Ann. Falsif., 10 (1917), No. 103-104, pp. 235-237, fig. 1).—A simple apparatus for routine analysis and its manipulation are described. It consists essentially of two colorimetric tubes, to one of which is attached at its lower end a piece of rubber tubing which is connected to a leveling bulb. This tube is used for the standard color solution, and by this arrangement the volume can be readily changed until the color corresponds with that of the unknown sample.

The calculation of the results is described.

Discontinuous extraction processes, L. F. Hawley (Jour. Indus. and Engin. Chem., 9 (1917), No. 9, pp. 866-871).

A simplified microcombustion method for the determination of carbon and hydrogen, L. E. Wise (Jour. Amer. Chem. Soc., 39 (1917), No. 9, pp. 2055-2068, figs. 4).—A modification of the Pregl¹ microcombustion method for the determination of carbon and hydrogen, in which 11- to 22-mg. samples are used and which does not require the use of a microbalance, is described. A sensitive analytical balance has been found to yield satisfactory results. The drying train of the original method has been modified, and the technique used in weighing and in carrying out the combustion has also been modified and standardized.

Analytical data obtained in the combustion of pure substances containing carbon, hydrogen, and oxygen indicate that the accuracy of the micromethod is comparable to that of the ordinary macrocombustion. Preliminary data indicate that the procedure, without further modifications, may be applicable to the microanalysis of a variety of nitrogenous organic compounds. The limitations and possible applications of the method are briefly discussed.

The possibilities and limitations of the Duclaux method for the estimation of volatile acids, L. J. Gillespie and E. H. Walters (Jour. Amer. Chem. Soc. 59 (1917), No. 9, pp. 2027-2055, figs. 3).—The authors have studied the Duclaux method in detail and have stated and verified the laws which must be assumed to calculate the results of analyses. Algebraic and graphic methods for the computation of results for mixtures of two or three acids have been described and the algebraic calculation for four or more acids indicated. Application of the methods to known mixtures shows that mixtures of two or three acids may be quantitatively analyzed without too great error. The errors, however, are in general too large for mixtures of four acids.

Data obtained show that the errors of the method are not proportional to the quantities of acid present. Mixtures containing four or more acids in significant quantities must be fractionated before applying the method into mixtures containing only three acids. "In order to apply the Duclaux method

<sup>&</sup>lt;sup>1</sup> [Abderhalden's] Handb. Biochem. Arbeitsmethod., 5 (1912), pt. 2, pp. 1307-1356.

to unknown mixtures it is necessary to establish that not more than three acids are present in significant quantities. This fact established, a distillation by the Duclaux method should suffice for both qualitative and quantitative analysis of the mixture. The methods of calculation do not depend on the form of the laws governing the rates of distillation of pure acids in aqueous solution, and therefore do not necessarily depend on the mode of distillation. The calculations may therefore be applied to distillations made in other ways, for instance, to steam distillations at constant volume. It is merely necessary to conduct all distillations both of pure acids and of mixtures in the same manner."

A modification of the McLean-Van Slyke method for the determination of chlorids in blood, G. L. FOSTER (Jour. Biol. Chem., 31 (1917), No. 3, pp. 483-485).—The method previously described (E. S. R., 34, p. 507) has been modified in that a freshly prepared 25 per cent solution of metaphosphoric acid is used for coagulating the proteins. The procedure is described as follows:

To 2 cc. of the sample in a 25-cc. volumetric flask, 20 cc. of water is added and then slowly, with stirring, 1 cc. of a freshly prepared solution of metaphosphoric acid. The flask is filled to the mark, well shaken, and allowed to stand for ten minutes with occasional agitation. The contents of the flask are then filtered and 10 cc. of the filtrate used for the determination, as described in the original method.

Studies of acidosis.—II, A method for the determination of carbon dioxid and carbonates in solution, D. D. VAN SLYKE (Jour. Biol. Chem., 30 (1917), No. 2, pp. 347-368, figs. 4).—A simple one-piece apparatus for the determination of carbon dioxid or carbonates in water solutions and its manipulation are described.

The principle of the method is that of vacuum extraction. The apparatus was designed especially for analysis of 1-cc. samples of blood plasma, but is indicated as being applicable to aqueous solutions in general, as well as for the determination of dissolved gases other than carbon dioxid. A microapparatus with which the carbon dioxid content of 0.2 cc. of plasma can be determined with an accuracy of one volume per cent, designed on the same principle, is also described. The entire analysis is performed at room temperature and requires only about three minutes.

The calculation of the results is described in detail.

Methods for the determination of saccharin in food products, A. Bonis (Ann. Falsif., 10 (1917), No. 103-104, pp. 210-218).—A general review of the-procedures for extracting saccharin and purifying the residue, and of methods of identification and quantitative determination.

Application of the cryoscopic method for determining added water in milk, J. T. Keister (Jour. Indus. and Engin. Chem., 9 (1917), No. 9, pp. 862-865).— It is concluded from the study that "the freezing-point figure of milk is the most constant one yet obtained and the safest basis upon which to draw conclusions as to the presence or absence of added water." Water added to fresh milk in excess of 5 per cent was detected with certainty by the freezing-point method. The use of sufficient formaldehyde for preservation was found to lower the freezing point. The test should be applied to the milk before any marked increase in acidity has taken place, since increased acidity affects the final results.

The freezing-point figures of the milk of 16 individual cows are submitted in tabular form, and the apparatus for determining the freezing point and its manipulation are described.

The determination of fat in certain milk products, C. K. Francis and D. G. Morgan (Jour. Indus. and Engin. Chem., 9 (1917), No. 9, pp. 861, 862).—Essentially noted from another source (E. S. R., 37, p. 507).

The estimation of unsaponifiable matter in oils, fats, and waxes, J. M. Wilkie (Analyst, 42 (1917), No. 495, pp. 200-202).—The following modification has been found more satisfactory than the procedure usually recommended for the determination of unsaponifiable matter.

A 5-gm. sample is saponified with 12.5 cc. twice-normal alcoholic potassium hydroxid for one-half to one hour, transferred to a separatory funnel with 50 cc. of water, and extracted with 40, 30, and 30 cc. portions of ether. The ether extracts are combined in a separatory funnel containing about 20 cc. of water. Without shaking, the wash water is run off, the ethereal solution then washed by shaking vigorously with 2, 5, and 30 cc. portions of water, evaporated to dryness, and the residue weighed.

For solid waxes, such as beeswax, a sample of 0.5 gm. is used, and in the saponification a few grams of castor oil is added. The procedure is then the same as described above, with the exception of the addition of 40 cc. of water at 30° C. instead of 50 cc. of cold water, and the extraction with 50, 40, 40, and 30 cc. portions of ether. A suitable correction for the known unsaponifiable content of the castor oil is made.

Data submitted indicate the accuracy of the modified procedure.

The thermal values of the fats and oils.—II, The sulphuric acid or Maumené number, J. W. Marden and M. V. Dover (Jour. Indus. and Engin. Chem., 9 (1917), No. 9, pp. 858-860, figs. 2).—Continuing previous studies (E. S. R., 34, p. 803), the authors propose a method for the calorimetric determination of the sulphuric acid number of fats and oils. The method is indicated as being simple, a single determination requiring only about one-half hour, and accurate to 0.5 per cent. The rise in temperature on addition of the acid, multiplied by the heat capacity of the system divided by the weight of the oil, gives the sulphuric acid number in calories per gram of sample. The concentration of the acid was found to affect the results, but a variation in the amount used had little effect so long as the concentration remained constant. The importance of the use of a standard concentration of acid in the test is indicated.

The construction of an inexpensive apparatus (calorimeter) and its standardization are described.

Tabulated data of the heats of reaction of 20 oils examined are submitted.

The pasteurization and biorization of fermented and unfermented grape and fruit juices, W. J. Baragiola (Schweiz. Apoth. Ztg., 55 (1917), No. 29, pp. 396-400).—The disadvantages of the pasteurization of grape and fruit juices are discussed, and some preliminary results of the sterilization of these juices with the biorizator (E. S. R., 31, p. 276; 35, p. 677) are submitted. The results obtained were entirely satisfactory, and no cooked flavor was imparted to the product as is the case when the juices are pasteurized. Some slight modifications of the biorizator were, however, found necessary.

It is intended to continue the study.

Aldehydes in wine, J. LABORDE (Ann. Inst. Pasteur, 31 (1917), No. 5, pp. 215-252).—From the results of the study reported it is concluded that the catalytic and physiological agents which are responsible for the formation of aldehydes in wine exercise their greatest influence in young wines during storage in casks. Under these conditions the wine is more or less in contact with the air. There are, however, certain factors which inhibit the production of aldehydes and which are favored by the exclusion of air. This condition is

indicated as being the reason for the small quantity of aldehyde in normally stored red wine. Formation of aldehydes in red wine is not considered to exercise any perceptible influence on the precipitation of tannin substances.

It is indicated that the aldehydes exercise not only a transitory influence but one which is wholly unfavorable to the aroma of red wines stored in casks. It is equally injurious to white wines, especially those which are deficient in sulphurous acid. Only those special wines in which part of the quality depends on an energetic oxidation are benefited by the formation of aldehydes, as it is favorable to the development of their characteristic aroma.

The data obtained in the study are submitted in tabular form and discussed. Chemical composition of "separated musts," W. J. Baragiola and J. B. Kleber (Landw. Jahrb. Schweiz, 31 (1917), No. 3, pp. 303-314).—Analytical data of so-called separated musts prepared from the juice of overripe fruits are submitted and discussed.

The juice of such fruits is deficient in tannic acid and consequently turbid, and proper fermentation does not take place in such musts. They may be clarified, however, by proper treatment and are then known as separated musts, the fermentation of which proceeds as satisfactorily as that of a normal must.

Sauerkraut industry of the United States, L. A. ROUND and S. C. COPPER-SMITH (Canner, 44 (1917), Nos. 16, pp. 48, 50; 17, pp. 48, 50; 18, pp. 52, 54; 19, p. 52; 20, pp. 48, 50).—This is a general discussion of the conditions necessary for the successful fermentation of sauerkraut.

Utilization of frozen and decayed potatoes, Schbibaux (Compt. Rend. Acad. Agr. France, 3 (1917), No. 26, pp. 716-718).—The use and value of frozen and decayed potatoes as a stock food and in some instances as human food is noted. A procedure which can be easily carried out on the farm, and which consists of washing, pulping, and drying the pulp, is briefly outlined.

A moderate-sized evaporator for fruits and vegetables, A. F. Barss (Oreg. Agr. Col., Ext. Bul. 213 (1917), pp. 4, figs. 4).—This bulletin describes the construction of a simple and efficient evaporator for drying fruits and vegetables.

Bacteriological study of the natural coagulation of the latex of Hevea brasiliensis, Denier and Vernet (Compt. Rend. Acad. Sci. [Paris], 165 (1917), No. 3, pp. 123-126).—The authors have isolated 26 species of facultative aerobes and anaerobic organisms from the natural coagulation of the latex. The organisms are indicated as being present in great numbers. The cultural and morphological characters of the organisms isolated are described.

Certain precautions necessary for a perfect coagulation of the latex are briefly outlined.

More about rice hull carbon, F. Zerban (La. Planter, 59 (1917), No. 6, pp. 93, 94).—This article reports the results of sugarhouse tests in which the new rice hull carbon was used for clarification. The results are considered entirely satisfactory and, while only of a preliminary nature, are indicated as having established the value of the new product.

Laboratory experiments carried out at the Louisiana Sugar Experiment Station have shown the rice hull carbon, properly prepared and purified, to have a very high decolorizing and deodorizing power which exceeds many times that of ordinary bone black. Its use extends over a large range. The impurities taken up by the carbon can be easily removed and the original decolorizing power restored.

Local processes of coconut oil extraction in the Philippines, C. A. GARDINER (*Philippine Agr. Rev.* [English Ed.], 10 (1917), No. 1, pp. 27-31, figs. 6).—This is a brief description of the machines and methods employed in the extraction of coconut oil in small mills owned and operated by the individual farmer.

## METEOROLOGY.

Monthly Weather Review (U. S. Mo. Weather Rev., 45 (1917), Nos. 5, pp. 203-266, pls. 12, figs. 14; 6, pp. 267-333, pls. 20, figs. 34).—In addition to weather forecasts, river and flood observations, and seismological reports for May and June, 1917; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during May and June, 1917; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 5.—City Smoke and Daylight Illumination Intensities (illus.), by H. H. Kimball and A. H. Thiessen; On Horizontal Halos (illus.), by Y. Tsuiji (reprinted); Solar Halo at Vicksburg, Miss., April 24, 1917, by W. E. Barron; Halo Phenomena April 8, 1917, at York, N. Y., by M. N. Stewart; Summer Types of Rainfall in Upper Pecos Valley (illus.), by C. Hallenbeck (see p. 808); Showers of Organic Matter, by W. L. McAtee (see p. 808); Records at the Abbe Meteorological Observatory Compared with Those at the Government Building, Cincinnati (illus.), by W. C. Devereaux; Winter Indoor Aridity in Topeka, Kans., by S. D. Flora; The Preparation of Precipitation Charts, by W. G. Reed and J. B. Kincer; Some New Instruments for Oceanographical Research.—Supplemental Note (illus.); Hail Squall of May 1, 1917, and Accompanying Weather, Baltimore, Md., by L. K. Hirshberg; Photographs of the Antler, N. Dak., Tornado of August 20, 1911 (illus.), by H. E. Simpson; and Some Researches in the Far Eastern Seasonal Correlations.—Second Note (illus.), by T. Okada (reprinted).

No. 6.—Peculiar Streak in Line with Kite Wire, by B. J. Sherry; The World's Air Routes and Their Regulation, by Lord Montagu, of Beaulieu (reprinted abs.); New England Snowfall (illus.), by C. F. Brooks (see p. 807); The Cold Spring of 1917 (illus.), by P. C. Day (see p. 808); Some Aspects of the Cold Period, December, 1916, to April, 1917, by R. C. Mossman (reprinted abs.); Accidental Pressure Variations in the United States, by A. J. Henry; The Tornadoes and Windstorms of May 25-June 6, 1917 (illus.), by H. C. Frankenfield; Meteorological Courses for Aeronautical Engineers.—[Syllabus of 10 Lectures by R. DeC. Ward]; Some Researches in The Far Eastern Seasonal Correlations.—Third Note, by T. Okada (abs.); Kristian Birkeland, 1867-1917, by C. Chree (reprinted); Use of the Divining Rod in the Search for Hidden Things, by O. E. Meinzer (reprinted); Desiccation of Africa, by R. L. Harger (reprinted abs.); and Effect of Humidification of a School Room on Intellectual Progress of the Pupils, E. L. Thorndike and P. J. Kruse (abs.).

Free-air data at Drexel Aerological Station.—April, May, and June, 1916, W. R. Blair et al. (U. S. Mo. Weather Rev. Sup. 7 (1917), pp. 51, pls. 3).—Detailed tabulated data are given on temperature, pressure, humidity, wind, and potential obtained in 140 free-air observations during a period of 91 days in which the mean altitude attained was 2,339 meters (7,672 ft.) above sea level.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander et al. (Massachusetts Sta. Met. Buls. 343-344 (1917), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1917, are presented. The data are briefly discussed in general notes on the weather of each month.

New England snowfall, C. F. Brooks (U. S. Mo. Weather Rev., 45 (1917), No. 6, pp. 271-285, pl. 1, figs. 29).—This is an amplification of an article which has already been noted from another source (E. S. R., 37, p. 16).

Summer types of rainfall in upper Pecos Valley, [N. Mex.], C. HALLENBECK (U. S. Mo. Weather Rev., 45 (1917), No. 5, pp. 209-216, figs. 5).—From a study of data showing the rainfall, May to September, inclusive, for 12 years, 1905-1916, the author concludes that, while the summer rains of this portion of the United States are essentially daytime rains, there is a preponderance of night rains over the limited area occupied by the upper half of the Pecos Valley, due wholly to the occurrence of a peculiar type of nonconvective rainfall which is described.

Showers of organic matter, W. L. McAtee (U. S. Mo. Weather Rev., 45 (1917), No. 5, pp. 217-224).—This article describes in some detail the various kinds of animal and vegetable matter, alive and dead, which are transported and distributed through the atmosphere. It is stated that the more spectacular phenomena of this kind, such as the distribution of live animals of various kinds, are the least important from the standpoint of the distribution of life. "The rains of larger animals have attracted much attention and excited wonder, but in many cases the animals have been dead; in others they were doomed to die because of falling in an unsuitable environment. Not often are all the conditions propitious for the species to secure a new foothold.

"The unobtrusive, but steady and widespread movement of minute eggs and spores by the atmosphere, however, is of great importance in distribution because these organic bodies are adapted to survive such transport; their numbers are so great and their dispersal so wide that some of them will necessarily fall in favorable places. The chances are, in fact, that every suitable environment will be populated."

The cold spring of 1917, P. C. DAY (U. S. Mo. Weather Rev., 45 (1917), No. 6, pp. 285-289, figs. 4).—The unseasonable cold weather which persisted to an unusual degree in nearly all portions of the country during a period of three weeks, beginning about April 24 and continuing to the middle of May, is Discussing the agricultural effects of the low temperature, the author states that "while low temperatures retarded the planting and germination of corn, cotton, and other spring crops, and delayed the growth of gardens and truck over the southern districts, the cool weather was not unfavorable to winter wheat and other hardy cereals which are reported to have greatly improved during the month. Likewise fruit buds which had largely remained dormant escaped damage from the prevailing cold, although severe frosts were not experienced as late in the month as in some previous years. However, the cool weather was unfavorable in that it caused crops generally to be backward, which at the end of May were estimated to be from one to three weeks late throughout the country. This increases the liability to damage by fall frost for such crops as have a long period of growth."

#### SOILS—FERTILIZERS.

Relation of movement of water in a soil to its hygroscopicity and initial moistness, F. J. Alway and G. R. McDole (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 8, pp. 391-428, figs. 2).—In experiments conducted at the Nebraska Experiment Station "17 soils, ranging from a coarse sand with a hygroscopic coefficient of 0.6 to a silt loam with one of 13.3, were placed in cylinders in three different degrees of moistness, 0.5, 1, and 1.5 times the hygroscopic coefficient, 1 in. of water was applied to the surface, the rate of movement during five days observed, and finally the moisture distribution at the end of this period determined.

"When placed in the cylinders the finer-textured soils showed a lower apparent specific gravity than the coarser, but within groups of somewhat similar texture this value was found to show no direct dependence upon the hygroscopicity.

"The moisture content of the moistened layer, even at the end of the first hour, was only from one-half to two-thirds the maximum water capacity, which shows that the latter has little significance as a direct index of the moisture retentiveness of a soil. The moisture content of the moistened layer fell much more rapidly with the finer-textured soils, at the end of 24 hours it being only between two and three times the hygroscopic coefficient, while in the coarser soils it varied from three to ten times the coefficient. At the end of the five days equilibrium had been practically attained in the finer-textured soils, but in the coarser ones this was far from being the case. The coarser the soil the more slowly was equilibrium reached.

"The rate of penetration showed little dependence upon the hygroscopicity, but was definitely affected by the moistness, the higher the initial moisture content of any soil within the limits employed the more rapid being the downward movement of water. The distance of penetration during the five days following the application of water increased with the initial moistness of the soil, but was not closely related to the hygroscopicity, owing partly to the slowness with which equilibrium is attained in the coarser soils.

"With the finer-textured soils the water content of the moistened layer was not distinctly affected by the initial moistness, but with the coarser members the drier the soil the wetter was the moistened layer. Provided that a period of high evaporation is to precede the next rain, the character of the weather immediately following a rain will have a greater effect upon the loss of moisture by evaporation in the case of a coarse than of a fine-textured soil.

"Glass tubes were filled with the same soils in the same three degrees of moistness and the lower ends placed in contact with water kept at a constant level. The rate of rise during eight or ten days was observed and the moisture in the uppermost layer of the moistened portion of the soil column at the end of this period determined. At first the rise was most rapid in the soils of low hygroscopicity, but the difference gradually lessened until those of intermediate hygroscopicity were in the lead. There was no definite dependence of the rise upon the hygroscopicity. No definite dependence of the rate of rise upon the initial moistness was shown, it being, in the case of the three moisture conditions studied, generally most rapid in the moistest condition and slowest in the intermediate.

"All the finer-textured soils showed the highest percentage of moisture at the head of the advancing moist layer when used in the driest condition, but the coarser members showed no difference. The moisture content of this moist layer shows a rather constant relation to both the hygroscopic coefficient and the moisture equivalent, being similar to the moisture retentiveness of the same soils.

"The relative rates and distances of penetration in the different soils are not similar to the relative rates and heights of capillary rise."

Origin of alkali, R. Stewart and W. Peterson (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 7, pp. 331-353).—In connection with the authors' well-known studies at the Utah Experiment Station of the origin of niter spots in soils (E. S. R., 36, p. 423), analyses were made of some 400 representative samples of sandstone, shale, "alkali," clay, and an ash consisting of a mixture of dry dust with crystals of "alkali" found just under the clay crust on the most affected parts.

"These investigations show a marked amount of water-soluble salts or alkali in the undistributed country rock with local accumulation wherever the movement of the underground water has caused a local concentration by seepage through the rock and deposition by evaporation. There is a marked variation in the amount of salts occurring in the country rock in any given geological series, but uniformly high results have been obtained at widely separated sections of the country, such as those found at Grand Junction, Colo.; Emery and Vernal, Utah; and Lyman, Wyo. There is a marked concentration of nitrates and alkali in the ashlike and alkali deposits in the uncultivated areas."

A tabulated summary of the average alkali material found in the country rock "brings clearly to mind the fact that in a widely disseminated form there are in the shales and sandstones of the Cretaceous and Tertiary of Utah, Colorado, and Wyoming enormous deposits of soluble salts consisting of the sulphates, chlorids, nitrates, and bicarbonates of calcium, magnesium, and sodium. In certain local areas these salts become concentrated so as to produce native alkali, or 'niter spots,' by the movement of the underground water without the instrumentality of the irrigation ditch. Wherever the shale is highly impregnated with the salts the evaporation of the water deposits the alkali salts on the surface in the form of an ashlike powder."

A preliminary soil census of Alabama and west Florida, R. M. HARPER (Soil Sci., 4 (1917), No. 2, pp. 91-107, fig. 1).—This census is based on all the soil surveys of the Bureau of Soils of the U. S. Department of Agriculture for Alabama and west Florida published up to the end of 1916.

Soil survey of the Healdsburg area, Cal., E. B. Watson, W. C. Dean, C. J. Zinn, and R. L. Pendleton (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1915, pp. 59, pls. 5, fig. 1, map 1).—This survey, made in cooperation with the California Experiment Station, deals with the soils of an area of 222,720 acres in the central and northern parts of Sonoma County, in western California. The area consists of relatively level valley lands and low hills surrounded by higher hills which are mainly nonarable.

"The soils of the Healdsburg area include those of residual origin, those derived through weathering from old unconsolidated valley-filling deposits, and those of recent alluvial origin." Including rough mountainous land and riverwash, 30 soil types of 15 series are mapped, of which rough mountainous land covers 31.8 per cent, Goldridge fine sandy loam 12.8 per cent, and Madera loam 6.6 per cent of the area.

Soil survey of Cumberland County, Me., C. VAN DUYNE and M. W. BECK (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1915, pp. 92, figs. 2, map 1).—This survey deals with the soils of an area of 545,920 acres in southern Maine, the physiographic features of which are those of an uneven country with little or no systematic arrangement of its hills, valleys, and plains. Only small local areas are poorly drained.

With reference to origin, the soils of the area are classed as "soils derived from glacial till, from terrace deposits, from estuarine and glacial-lake deposits, from alluvial flood-plain deposits, from accumulations of organic matter, and miscellaneous nonagricultural. In all, 10 series with 21 soil types, 4 phases, and 4 miscellaneous types have been mapped." Of these the Gloucester sandy loam, Orono silt loam, Gloucester stony sandy loam, and the Merrimac sandy loam cover 27.3, 15.6, 15.5, and 11.5 per cent of the area.

The formation and characteristics of Massachusetts peat lands and some of their uses, A. P. Dachnowski (Trans. Mass. Hort. Soc.. 1917, pt. 1, pp. 29-

45).—This is an address delivered January 27, 1917, which was illustrated by means of lantern slides and samples of peat material, and is apparently intended to give the results of a reconnoissance of the peat lands of Massachusetts. It is concluded that the inequality in the character of the peat lands encountered and in the strata of their materials renders a more detailed study advantageous in their agricultural utilization.

"Information concerning the seasonal variations in the water table, the nature of the salt constituents, and the circumstances in the field conditions which lead to the augmentation or diminution of soluble constituents is of prime importance, the effect of any accumulation of iron compounds especially requiring attention in certain cases. The relation of cropping system to the several kinds of peat lands if ignored would be to the disadvantage of the real agricultural value of certain peat lands. Field trials are the more correct means under the existing conditions on the peat lands to determine the choice of crop varieties, seeding mixtures, etc., and the cultural practices to be followed."

The oxidizing power of some soils in Deli, J. A. Honing (Bul. Deli Proefstat. Medan, No. 8 (1917), pp. 8).—Tests of the Gerretsen method of determining the oxidizing power of soils (E. S. R., 35, p. 624) on the dry soils of Deli proved it to be impracticable and to give contradictory results on these soils. Frequently the hydrogen iodid value was high for samples taken at 1 or 2 ft. depth and low for surface soils having a high percentage of humus. The failure of the method on the nonirrigated soils of Deli is attributed to the presence of large quantities of humus and the irregular distribution of the ferric iron.

Variation in the chemical composition of soils, W. O. Robinson, L. A. Steinkoenig, and W. H. Fry (U. S. Dept. Agr. Bul. 551 (1917), pp. 16).—This bulletin presents complete analyses of 45 samples of soil, representing 18 distinct soil types distributed in four provinces. These, with the analyses of 24 samples previously noted (E. S. R., 31, p. 719), are discussed with reference to variation of all samples, variation in composition within a soil province, variation of the same type, and the bearing of the limit of error in analysis on the interpretation of analytical data.

"It is thought that the analyses discussed represent nearly the extremes in composition of soils in the regions in which the samples were taken. Marked resemblances in composition of soils from the same province are pointed out. It is shown that some samples of the same type differ considerably in chemical composition. It is also shown that some soils of different types may resemble each other in chemical composition as closely as different samples of the same type. It is pointed out that the unavoidable error in analytical operations is in many cases of such magnitude that when analyses are stated in pounds per acre differences of several hundred pounds of some constituents are not significant."

A soil sampler for bacteriological and chemical purposes, J. R. Neller (Soil Sci., 4 (1917), No. 2, pp. 109-113, figs. 3).—A soil sampler, devised at the New Jersey Experiment Stations, is described and diagrammatically illustrated.

The sampling tube is  $3\frac{1}{2}$  ft. long and has an inside diameter of  $1\frac{1}{4}$  in. It is divided into two parts, a and b. Piece a is 11 in. long and has a point made so that the core slides easily up through the tube. The inner shoulder above the cutting edge is about  $\frac{1}{3}$  in. wide. Piece a is attached to piece b by means of a bayonet, or groove and key joint, made so that it closes and tightens when the upper part of the tube is turned to the right. A slight twist to the left enables one to detach the lower piece and remove the core of soil. The shoulders of

this joint taper slightly into each other so as to come together and take up any looseness resulting from wear. The cleaning tube has an outside diameter that permits it to slip easily but snugly through the surface shield.

The use of the sampler is also described.

The influence of available carbohydrates upon ammonia accumulation by microorganisms, S. A. Waksman (Jour. Amer. Chem. Soc., 39 (1917), No. 7, pp. 1503-1512).—Experiments conducted at the University of California on the influence of carbohydrates on ammonia and amino nitrogen accumulations by soil microorganisms are reported. The organisms studied were Aspergillus niger and Citromyces glaber, isolated from soil by the author.

It was found that "the effect of sugar on the accumulation of ammonia by A. niger is marked. Where the sugar was absent the organism made a rather slow growth, as shown by the weight of the mycelium, but the ammonia accumulated in large quantities from the third till the sixteenth day, the amount increasing rapidly, so that on the sixteenth day about a half of the total nitrogen of the medium was in the form of ammonia. Where the sugar was present the ammonia accumulated only in very small quantities, while the weight of the mycelium increased rapidly until the seventh day, when autolysis set in and the weight of the fungus body began to decrease. The amount of ammonia accumulated was small when the organism grew rapidly; but as the maximum of growth was reached, which was also accompanied by the utilization of all the sugar in the medium, the ammonia began to accumulate very rapidly."

The same results were obtained with  $C.\ glaber$ , the excess of sugar corresponding to a decrease in the amount of ammonia present in the medium. "In the production of amino nitrogen  $C.\ glaber$  behaves in an entirely different manner from  $A.\ niger$ ; it was found that many organisms which are not able to reduce the proteins to ammonia, whether in the presence or absence of available carbohydrates, may split the proteins into amino acids which accumulate in the medium.

"This experiment shows again that, when available carbohydrates are present, the organism will utilize all the nitrogen split off from the protein for its own metabolism; while in the absence of available carbohydrates, or where these have been used up, the protein molecule will be attacked not only for its nitrogen content but also for its carbon content."

Effect of paraffin on the accumulation of ammonia and nitrates in the soil, P. L. Gainey (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 7, pp. 355-364).—In experiments at the Kansas Experiment Station paraffin and Parowax in thin shavings and paraffin oil were added to a soil having a vigorous ammonia and nitrate-forming flora at the rate of 2 gm. per 100 gm. of soil. In certain cases also the insides of the 500-cc. bottles used in the incubation test were paraffined or parowaxed. In certain cases no additions were made of nitrogen or calcium carbonate. In other cases nitrogen was added in the form of cotton-seed meal and ammonium sulphate at rates of 50 mg., and calcium carbonate at the rate of 0.5 gm. per 100 gm. of soil.

In the tests in which no nitrogen was added, and regardless of whether calcium carbonate was added, paraffin in the three forms used not only inhibited the accumulation of ammonia and nitrate nitrogen, but caused that which was present at the beginning of the experiments to disappear. This effect was maintained for 13 weeks and even longer, and regardless of whether the paraffin was intimately mixed with the soil or simply lined the inner wall of the container.

When nitrogen was added in the form of cottonseed meal, there was vigorous formation of ammonia and nitrate in the presence of paraffin, but these disappeared so rapidly that "it is impossible to say whether such formation was equally as rapid as in the absence of paraffin." In no case did the quantity of ammonia or nitrate nitrogen, where Parowax or paraffin had been added, approach the quantity in the controls at the end of two weeks. The inhibitory effect of the paraffin oil was more marked than that of other forms of paraffin during the early stages of incubation. The effect of the oil appears to be quite largely an inhibition of formation rather than a disappearance of ammonia and nitrate nitrogen.

"When ammonium sulphate was added to the soil either with or without calcium carbonate, all three forms of paraffin exerted a very marked effect upon the accumulation of nitrate nitrogen. The decreased accumulation of nitrate nitrogen was not so evident during the early stages of incubation except with paraffin oil. With the oil the effect again seems to be to retard nitrification, the quantity of active nitrogen [NO<sub>3</sub>+NH<sub>3</sub>] approaching very closely that in the controls. Parowax and paraffin, however, not only decrease the accumulation of nitrate nitrogen but also bring about a large reduction in the quantity of active nitrogen. The reduction in active nitrogen occasioned by the various forms of paraffin is not nearly so rapid where ammonium sulphate was added as where nitrogen in the form of cottonseed meal was added."

Further experiments with larger amounts of soil in paraffined 2-gal. earthenware containers showed that "no ordinary sized container used for cultural purposes can be protected with a coating of paraffin, as in these experiments, without the available nitrogen content throughout the whole mass of soil being affected."

Nitrates and nitrification in relation to cultural practices and plant growth, H. A. Noyes (Abs. Bact., 1 (1917), No. 1, pp. 38, 39).—A summary is given of the first two years' results of soil bacteriological investigations which are being conducted in an experimental orchard where different cultural practices are under direct comparison. The objects of these investigations are first, to find out if the behavior of the trees can be directly correlated with the activities of the bacteria in the soil, and second, to determine the effect of the activities of the bacteria on the soil.

"The results are as follows: The nitrates in the field correlate with tree growth (circumference gains). The lower nitrate content under field conditions does not mean lower nitrate content after incubation. The field nitrates when compared with the nitrates after incubation give the nitrifying efficiency of the organisms under field conditions." It is concluded that "knowledge of the nitrate content of field soil may throw more light on the activities of nitrifying bacteria than the nitrification test itself."

A program of soil improvement for New York State, E. O. FIPPIN (N. Y. State Col. Agr., Cornell Univ. Ext. Bul. 15 (1917), pp. 499-534, figs. 5).—"The purpose of this bulletin is to point out the primary elements of a comprehensive system of soil improvement, and to propose a program of work that will coordinate and unify, so far as that is now practicable, the field study of soils."

Barnyard manure and products of decomposition, H. Murphy (Okla. Agr., 5 (1917), No. 9, pp. 13-16, 18).—This is a brief summary of experience at several of the State experiment stations and at certain foreign experiment stations.

Manure from the sea, E. H. JENKINS and J. P. STREET (Conn. State Sta. Bul. 194 (1917), pp. 3-13, figs. 7).—This bulletin treats of the manurial value of

seaweeds and marine mud. Analyses of samples of these materials from the New England coast, made at the Rhode Island, Massachusetts, and Connecticut experiment stations, are given in the following table:

Average composition of seaweeds, calculated to 75 per cent moisture.

Kind of material.	Num- ber of an- alyses.	Organic matter.		Phos- phoric acid.	Potash.	Lime.	Mag- nesia.
•		Per ct.	Per ct.	Per ct.		Per ct.	Per ct.
Laminaria saccharina		1(19.76)	0.39	0.13	0.51	0.83	0. 35
L. digitata	7		. 45	. 12	. 62	. 69	. 38
Ascophyllum nodosum	11	(19.47)		(0.02)		. 49	. 38
Fucus vesiculosus	12	(19. 34)		. 12	. 50	. 47	. 30
Chondrus crispus	9	(18, 75)		. 13	1.15		
Zostera marina		(10, 90)	. 41	. 15	. 42	. 91	. 30
Rhodymenia palmata	1		. 68	. 17	1.98	. 87	. 16
Phyllophosa membranifolia	3		. 80	. 11	. 72	3, 66	. 50
Cladostephus verticellatus	1		. 39	. 19	1. 23	. 75	. 31
Polyides rotundus	1		. 82	. 15	. 36	. 60	. 18
Ahnfeldtia plicata	1		. 42	. 09	. 88	. 22	. 28
A hnfeldtia plicata	1		. 98	. 24	1.74	. 31	. 24
Sea lettuce	1		. 33	.06	. 48		
Coarse sponge	1		1.04	. 25	. 29	. 14	. 25

<sup>&</sup>lt;sup>1</sup> Most figures in parentheses are results of single analysis and not average.

A comparison of average analyses of seaweed, New York horse manure, and cow manure with litter shows "that the average seaweed contains less organic matter, nitrogen, and phosphoric acid than New York horse manure, and compared with cow manure it has about the same amount of nitrogen, much less phosphoric acid, and more potash. Seaweeds are relatively deficient in phosphoric acid. . . . Eelgrass is generally regarded as inferior to the rockweeds as manure, though the composition of the fresh material is not strikingly different."

Analyses of 9 samples of marine mud from various places on the Connecticut shore showed an average moisture content of about 48 per cent, organic matter 3.95, and nitrogen 0.15 per cent. In four of these samples further determinations average, as follows: Potash, 0.35 per cent; soda, 0.72; lime, 0.43; magnesia, 0.52; phosphoric acid, trace; chlorin, 0.93; and sulphuric acid, 0.53 per cent. It is stated that although the percentages of organic matter, nitrogen, and potash in marine mud are small, "applications of from 1,000 to 2,000 bu, per acre have given excellent results, due in part, no doubt, to the action of the mud as an amendment, making the soil more retentive of water, and perhaps in part also to the action of salt."

The value of coconut poonac as manure, M. K. Bamber (Dept. Agr. Ceylon Leaflet 1 (1917), folio).—Analyses of ordinary coconut poonac showed a content of nitrogen 3.33 per cent, phosphoric acid 1.47, potash 1.29, lime 0.9, and soda 1.17 per cent.

Experiments with humogen, M. H. F. Sutton (Reading, England: Sutton & Sons [1917], pp. 12, flgs. 14).—Experiments with mustard, Italian rye grass, and dwarf French beans to test the fertilizing value of humogen and also to compare it with barnyard manure and complete fertilizers are reported.

No great success attended the use of commercially manufactured humogen, although results were obtained with humogen made in the laboratory which were second only to those obtained with a complete fertilizer. "So far as the results of these tests show, it would appear that, however satisfactory humogen may be when prepared in the laboratory, some difficulty as yet exists in manu-

facturing this fertilizer efficiently on a commercial scale. The question also arises whether, when standardized, it can be placed on the market in a sufficiently concentrated form and at a price low enough to bring it within the reach of large users of fertilizers."

The industrial chemist and the fertilizer crisis, H. C. Lint (*Chem. Engin. and Manfr.*, 25 (1917), No. 3, pp. 86-89).—The author discusses the fertilizer problem from the standpoint of the industrial chemist, and discusses peat and muck as sources of organic ammoniates.

The effect of ammonium sulphate on soil acidity, F. E. Allison and R. C. Cook (Soil Sci., 3 (1917), No. 6, pp. 507-512, fig. 1).--Experiments conducted at Rutgers College are reported in which it was found that "the increases in acidity in five greenhouse soils and a quartz sand receiving no nitrogenous fertilizer were practically the same during the course of a year whether these soils were cropped or kept in fallow. The quartz sand showed the smallest increase in acidity and a loam soil the largest, but there was no relation between the acid accumulation and the soil texture. The increases in acidity in the presence of ammonium sulphate were markedly higher than in the check pots. The partial removal of the nitrogen added decreased the acidity to an appreciable extent in the quartz sand and in the heavy clay soil, increased it in the loam, and left it practically the same in the other three soils. The average increase in acidity in the soils used, exclusive of the quartz sand, was 4,140 lbs. of calcium oxid per 3,000,000 lbs. of soil where no crop was grown, and 4,240 lbs, where four crops of buckwheat were harvested. On the average, the increase in acidity produced by ammonium sulphate in greenhouse pots was about 80 lbs. of calcium oxid for 100 lbs. of ammonium sulphate applied."

The fixation of atmospheric nitrogen, D. Florentin (Génie Civil, 70 (1917), Nos. 20, pp. 319-322; 21, pp. 333-337; 22, pp. 353-355; 23, pp. 369-372; 24, pp. 384-386, figs. 14).—This article reviews recent processes and discoveries relating to the industrial fixation of atmospheric nitrogen for agricultural and industrial use.

Some conditions affecting the value of calcium cyanamid as a manure, T. D. Mosscrop (Jour. Agr. Sci. [England], 8 (1917), No. 2, pp. 178–181).—Belljar and pot experiments with lettuce, turnips, barley, and wheat to determine the cause of the injurious influence of calcium cyanamid led to the conclusion that "any injurious effect on germination when calcium cyanamid is used is due to the formation of free ammonia produced at first more rapidly than it can be absorbed by the soil." It was further found that the injurious action disappeared eight days after the manure had been applied to a moist soil. "Any danger to nonoily seeds or those with a thin testa can be avoided by applying the calcium cyanamid a week before sowing the seeds."

The value of Thomas slag phosphate for neutralizing soil as well as for supplying phosphorus, B. L. Hartwell, F. R. Pember, and S. C. Damon (Rhode Island Sta. Bul. 171 (1917), pp. 3-34, pl. 1).—Experiments are reported the main object of which was to help furnish a basis for the adoption of analytical methods suited to the inspection of the various grades of Thomas slag phosphate from the standpoint of their agricultural value.

In experiments with barley, beets, and lettuce to determine the value of Thomas slag phosphates from different sources for neutralizing acid soils, using chemically pure, precipitated calcium carbonate as a standard of comparison, it was found that the calcium carbonate did not give results markedly superior to those given by the slags with the first two crops. "With the lettuce, however, the conditions were such that, for about the same amount of calcium oxid

applied, that in the slags was only about a third as effectual as in the other form. . . .

"Data concerning the relative availability of the phosphorus in slags and other phosphates were secured by four pot experiments with dwarf Essex rape and one with Japanese millet. A field experiment with these two crops was also conducted for two years. The later experiments, both in the pots and field, were carried out according to directions furnished by the basic slag committee of the Association of Official Agricultural Chemists. The use in the pots of a preceding crop of crimson clover as a green manure did not increase the relative availability of the phosphorus in the insoluble phosphates, slag, and raw rock phosphate, or floats, in comparison with that in the soluble sources. In the pot experiments, although the slags compared very favorably with the soluble sources, the floats were decidedly inferior; even in large applications the latter material failed to supply the needs of the plants. From soil to which no phosphorus was added the millet absorbed per pot more than twice as much as the rape did. . . . Even when applied in the most available source more than four-fifths of the phosphorus became inaccessible to the first crop planted after its application.

"In the field experiments with both millet and rape results were obtained for the year in which the various sources of phosphorus were applied as well as the after-effects in the following year. The raw rock phosphate was much less available than the other sources of phosphorus. . . . Basic phosphate yielded somewhat less than the other slags, which compared favorably with the soluble phosphates.

"It would seem from the results of the experiments . . . that if water-soluble phosphate is considered entirely available, then a laboratory method for determining the availability of Thomas slag phosphate should include the use of some solvent which would dissolve nearly all of the phosphorus."

The rate of reversion of mixtures of superphosphate with basic slag and rock phosphates, G. S. Robertson (Jour. Soc. Chem. Indus., 36 (1917), No. 12, pp. 626-628).—Experiments with mixtures of equal parts of 26 per cent water-soluble superphosphate and 26 per cent citric-soluble basic slag led to the conclusion that "on the whole it can not be said that a superphosphate and basic slag mixture has anything particular in its favor. If the basis of the mixture is one-half 26 per cent superphosphate and one-half basic slag, it is clear that if the slag contains 2 per cent of caustic lime practically all the water-soluble phosphate in the mixture will revert in a few hours."

Experiments with equal parts of 26 per cent superphosphate and Gafsa rock phosphate showed that "the water-soluble phosphate in the mixture reverts to a much less extent than in the slag and superphosphate mixture. The reversion is, comparatively speaking, so small that there would be no serious objection to farmers making and applying such a mixture. . . . There seems to be no serious difficulty in the way of manufacturers making such a mixture (1 of superphosphate to 1 of rock phosphate) and selling it with a guaranty of water-soluble phosphate, total phosphate, and, if advisable, citric-soluble phosphate."

Phosphate rock in 1916, R. W. Stone (U. S. Geol. Survey, Min. Resources, U. S., 1916, pt. 2, pp. 29-41).—This report states that "the quantity of phosphate rock marketed in the United States in 1916 was 1,982,385 long tons, valued at \$5,896,993, an increase of 146,718 tons in quantity and of \$483,544 in value over the production of 1915. This increase was comparatively small but it indicates an improvement in the industry, and suggests that in spite of the curtailment in the exports the production of former years may in time be approached. . . .

"The quantity mined in 1916 was 2,169,149 tons. Compared with the quantity mined in 1915, which was 1,935,341 tons, this was an increase of 12 per cent, as against a decrease of about 27 per cent in 1915 from 1914. In Florida the increase was about 17 per cent, 24 companies operating in 1916 instead of 17, as in 1915. In South Carolina there was a decrease of 46 per cent and in Tennessee an increase of 5 per cent. In Kentucky 1 producer reported rock mined. The production in the Western States decreased 55 per cent. . . .

"The western phosphate field includes about 2,500,000 acres, in which there are about 5,750,000,000 tons of high-grade rock within minable depth (5,000 ft.) of the surface, and in addition several billion tons of rock carrying from 15 to 40 per cent of tricalcium phosphate. Throughout most of the western field there is a main bed from 3 to 6 ft. thick which runs over 65 per cent in tricalcium phosphate. The workable deposits occur chiefly in public lands of the United States. The character and mode of occurrence of the rock are such that for the most part it must be mined by underground methods rather than by open pits. The rock can be ground and treated with acid, however, without the preliminary washing and drying which increase the cost of production of eastern phosphates."

Data on foreign sources of phosphoric acid are also given.

Potash in agriculture.—III, Further researches, B. C. Aston (Jour. Agr. [New Zeal.], 14 (1917), No. 6, pp. 440-447).—In a further discussion of the potash situation in New Zealand (E. S. R., 37, p. 218), it is pointed out that flax waste, wood askes from sawmills, hedge clippings, weeds, and liquid stock excreta are some of the more important sources of potash in New Zealand which are now disregarded or wasted. It is also thought that bracken as a source of potash is worthy of investigation, as studies have shown that New Zealand bracken in the young stages contains as much potash as Scottish bracken and gives a higher yield per acre.

The recovery of potash from beet sugarhouse waste liquors, H. E. ZITKOWSKI (Sugar [Chicago], 19 (1917), No. 7, pp. 256-258; Metallurg. and Chem. Engin., 17 (1917), No. 1, pp. 17-19).—It is pointed out in this article that technically the recovery of the potash from beet sugarhouse waste liquors is a comparatively simple and perfectly feasible problem. "It is simply one of evaporating the dilute liquors as economically as practical, charring the residue to produce the crude ash, and leaching and recrystallizing if this is desired. The quantities of water to be evaporated, however, are large, the necessary equipment costly, and commercially such a procedure has possibilities only during war prices."

Concentrated potash a by-product of cement mill (Engin. News-Rec., 78 (1917), No. 13, pp. 630-632, figs. 3).—Experience at a cement plant at Riverside, Cal., indicates that the possibilities of recovery of potash as a by-product in Portland cement manufacture are that 90 per cent of the potash contained in the raw mix can be volatilized, 10 per cent remaining in the clinker and 80 per cent being caught by the dust collector. Including filter losses, it is considered conservative to expect the recovery in the form of concentrated salt of 663 per cent of the potash originally contained in the raw cement mix. A 100-ft. rotary kiln, it is stated, may produce from 4 to 7 tons of dust daily, the average potash content of which may range between 4 and 10 per cent.

With reference to the mechanical features of the process, the dust is drawn from bins under the electrical treatment into tanks, where it is put into solution by agitation in water of not less than  $85^{\circ}$  C., at a concentration of not over 5 per cent  $K_2O$ . The temperature soon rises to the boiling point, due to the hydration of the lime, and the potash goes rapidly into solution, the whole operation

of extracting the water-soluble potash from 7 tons of dust being accomplished in less than 50 minutes. Under filter-press treatment a cake is formed and removed, and the remaining solution evaporated and the salt collected for grinding and sacking. Six lbs. of potassium sulphate is now being recovered at the plant for every barrel of clinker burned, which at present prices is worth from 40 to 50 cts. per barrel of cement produced.

The possibilities of developing an American potash industry, R. K. Meade (Metallurg. and Chem. Engin., 17 (1917), No. 2, pp. 78-87; abs. in Sci. Abs., Sect. B—Elect. Engin., 20 (1917), No. 10, p. 367).—This is a rather comprehensive survey of the present potash situation in the United States and a discussion of future possibilities along this line.

The author believes "that the largest future source of cheap potash available in this country is in the iron industry and the cement industry. Germany is reported to have \$150 invested in her potash mines and equipment for every ton of potash produced annually. On this basis \$37,000,000 would be needed to produce the 250,000 tons of potash imported into this county. . . . The expenditure of this amount of money in this country in these two industries alone would result in the recovery of potash now lost amounting to nearly 200,000 tons. The balance could easily be obtained from the evaporation of lakes and brines, from beet-sugar waste, and from some of the processes now proposed for the manufacture of potash direct from feldspar or glauconite."

A key to the soil for better crops is soluble ground limestone (Indianapolis, Ind.: Indiana Agr. Ground Limestone Assoc. [1917], pp. 15).—This pamphlet briefly describes the use of ground limestone on soils.

Lime report, 1916, J. W. Kellogg et al. (Penn. Dept. Agr. Bul. 294 (1917), pp. 33).—This is the report of the official inspection and analysis of agricultural lime in Pennsylvania for 1916.

Fertilizer report, August 1 to December 31, 1916, J. W. Kellogg (Penn. Dept. Agr. Bul. 288 (1917), pp. 71).—This is a report of the official inspection and analysis of fertilizers in Pennsylvania for the period named.

#### AGRICULTURAL BOTANY.

The botany of crop plants, W. W. Robbins (Philadelphia: P. Blakiston's Son & Co., 1917, pp. XIX+681, figs. 262).—This book, intended for agricultural and nonagricultural students, is designed to give a knowledge of the common orchard, field, and garden crops, more than 100 being treated. After an introductory part in which the fundamentals of plant structure, function, activity, and classification are dealt with, the different crops are taken up in the order of their families, the habits of the plants, their distinctive characteristics, distribution, production, and uses being described. Keys are given of the principal economic types that will aid the student in recognizing and identifying forms with which he is unfamiliar.

Important range plants: Their life history and forage value, A. W. Sampson (U. S. Dept. Agr. Bul. 545 (1917), pp. 63, pls. 56).—The results are given of a study of the habits, requirements, and life history of more than 50 species of forage plants in the Wallowa National Forest in northeastern Oregon. Preliminary information regarding the palatability of the plants was obtained by observing sheep while feeding, and afterwards the relative value of the individual species was determined by studying their abundance, distribution, time of flower-stalk production, aggressiveness, reproduction (both vegetative and by seed), their palatability and nutritiousness at various times during the grazing season, and their ability to withstand trampling.

The data obtained relative to the life history of the different forage species are said to have made possible the adoption of what is known as the deferred or rotation grazing system in this forest.

Tables are presented giving the soil moisture requirements, time of flower-stalk production, time of seed maturity, and seed viability of the different species investigated.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from January 1 to March 31, 1914 (U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 38 (1917), pp. 105, pls. 10).— This inventory includes importations of about 700 lots of seeds and plants.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from April 1 to June 30, 1914 (U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 39 (1917), pp. 183, pls. 10).—A list is given, together with economic notes, on about 1,000 importations of seeds and plants.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from July 1 to September 30, 1914 (U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 40 (1917), pp. 110, pls. 10).—This gives accounts of about 640 introductions, most of the material having been received from China, India, and Brazil.

New or noteworthy plants from Colombia and Central America, VI, H. PITTIER (U. S. Nat. Mus., Contrib. Nat. Herbarium, 18 (1917), pt. 6, pp. 225-259+X, pl. 1, figs. 7).—This paper is a continuation of a series of studies by the author on the flora of Colombia and Central America (E. S. R., 34, p. 827).

The Middle American species of Lonchocarpus, H. PITTIER (U. S. Nat. Mus., Contrib. Nat. Herbarium, 20 (1917), pt. 2, pp. 37-93+X, pls. 6, figs. 437.—A description is given of the species of Lonchocarpus known to occur in Central America and Mexico.

The families and genera of the bacteria, C. E. A. Winslow, Jean Broad-Hurst, R. E. Buchanan, C. Krumwiede, Jr., L. A. Rogers, and G. H. Smith (Jour. Bact., 2 (1917), No. 5, pp. 505-566).—A preliminary report is given of the committee of the Society of American Bacteriologists appointed to consider the characterization and classification of bacterial types. An outline of the families and genera of bacteria is presented. The committee proposes the recognition of four orders of Schizomycetes, the Eubacteriales embracing 8 families and 31 genera. The adoption is recommended of the principles of the so-called Vienna Code of Botanical Nomenclature, with the exception of the requirement of Latin descriptions. It is also recommended that the date of publication of the third edition of Zopf's Spaltpilze be taken as the date for the beginning of bacteriological nomenclature in determining priority, except for a list of genera conservanda to be adopted by the society at its 1918 meeting.

Is symbiosis possible between legume bacteria and nonlegume plants? T. J. Burrill and R. Hansen (*Illinois Sta. Bul. 202 (1917)*, pp. 113–181, pls. 10, flgs. 8; abs., pp. 4, flg. 1).—This bulletin gives an account of investigations on legume bacteria and an attempt to develop symbiosis between legume bacteria and nonlegume plants similar to that which exists between *Pseudomonas radicicola* and leguminous plants.

Studies preliminary to the attempt to develop strains of bacteria that would exist in symbiosis with nonlegume plants showed that the nodule bacteria taken from the roots of leguminous plants may be divided into 11 groups according to the host plants to which they have become specifically adapted. By means of cultures, the authors have been able to isolate *P. radicicola* from all of the subfamilies of Leguminosæ, and while the various nodule bacteria exhibit sero-

logical and cultural differences which are permanent, yet in other characteristics they are so alike that it is considered best to regard the adapted forms as varieties of a single species. The nodules occurring on Ceanothus, Cycas, Alnus, and Myrica are said not to be caused by *P. radicicola*, those on Ceanothus differing morphologically from those found on the Leguminosæ. The authors do not consider conclusive the evidence that the nodules on Elæagnus and Podocarpus are caused by legume bacteria, nor is the proof conclusive that any of these nonlegume plants are concerned in the fixation of atmospheric nitrogen.

Extensive experiments were conducted in an attempt to infect nonlegume plants with nodule bacteria, always with negative results, and it is claimed that no conclusion can be drawn as to the possibility or probability of developing or finding nodule bacteria that will grow on nonlegume plants.

An extensive bibliography of the subject is appended.

The abstract is by A. L. Whiting.

The behavior of self-sterile plants, E. M. East (Abs. in Science, n. ser., 46 (1917), No. 1183, pp. 221, 222).—According to the author, there are two problems connected with the inheritance of self-sterility in plants. One is the relation between self-sterile and self-fertile plants, the other the behavior of self-sterile plants when crossed together. In Nicotiana self-fertility is completely dominant over self-sterility. Either of the self-sterile species N. alata or N. forgetiana may be crossed with the self-fertile species N. langsdorffi, resulting in each case in an F<sub>1</sub> generation which is completely self-fertile. The F<sub>2</sub> plants are said to show the usual monohybrid ratio of 3 self-fertile to 1 self-sterile.

Discussing the results obtained in his investigations, the author concludes that the behavior of self-sterile plants in intercrosses is regulated by several transmissible factors, all of which are distinct from the single basic factor for self-sterility and which presumably may be carried by self-sterile plants. A plant homozygous for self-sterility can neither be fertilized by its own gametes nor by the gametes of any other self-sterile plant of like constitution as regards these regulation factors, but any two plants differing in these regulatory factors are cross-fertile.

Twin hybrids from Enothera lamarckiana and E. franciscana when crossed with E. pycnocarpa, G. F. Atkinson (Abs. in Science, n. ser., 46 (1917), No. 1183, p. 222).—According to the author, when E. lamarckiana is crossed with E. pycnocarpa, there is a splitting in the F<sub>1</sub> generation with the production of twin hybrids. One of the twins is characterized by the pycnocarpa type, while the other is designated as a lamarckiana type. These twin types are fixed in the first generation, and are repeated in the F<sub>1</sub> and probably in the following generations in accordance with the usual behavior of twin hybrids determined by De Vries.

When E. franciscana and E. pycnocarpa are crossed, there is said to be a splitting in the  $F_1$  with the production of twin hybrids, and in the  $F_1$  generation there is a one-sided splitting similar to that which occurs in the  $F_2$  of twins from E. hookeri and E. lamarckiana, as described by De Vries. In this second grouping the pycnocarpa type twin is said to have a hybrid constitution, while the franciscana type of this generation is fixed in the  $F_1$  and repeats itself in the  $F_2$ . The franciscana twin is believed to carry the pycnocarpa factors, but in a subordinate or permanently latent condition.

Naming American hybrid oaks, W. Trelease (Abs. in Science, n. ser., 46 (1917), No. 1184, p. 244).—In a study of American oaks, the author has investigated 38 known or probable hybrids among the oaks of the United States. To the number of accepted hybrids already recorded two are added in this paper.

So far no cases of hybridity have been observed in which a species of the white oak group has intercrossed with a species of the red oak group.

The anatomy of woody plants, E. C. Jeffrey (Chicago: The University of Chicago Press, 1917, pp. X+478, pl. 1, figs. 307).—In this book the author treats of the anatomy of vascular plants, with special reference to its historical and experimental aspects. In former standard works upon this subject the anatomy of existing forms is treated, but the author of the present work supplies many paleobotanical and developmental data that are fundamentally important for an understanding of the evolution of plant organization. A chapter on anatomical technique is given that may be used as a guide to the preparation of material for study.

Ecology and physiology of the red mangrove, H. H. Bowman (Abs. in Science, n. ser., 46 (1917), No. 1184, p. 245).—A report is given of an examination of the microscopic structure of the various tissues of the red mangrove, the material having been collected in the Gulf of Mexico along the lower Florida Keys. Particular attention has been paid to the presence of intercellular stone cells and to the occurrence of tannin cells. The physiological relations of transpiration and absorption of these plants growing in sea water and all dilutions of it, as well as in fresh water, have been studied.

The author has deduced the law that the transpiration of these plants varies directly as the concentration of the medium. It was also found that there is a definite relation between the amounts of sugar and tannin in the hypocotyls at different stages of growth of the plants.

The chemical basis of regeneration and geotropism, J. Loeb (Science, n. ser., 46 (1917), No. 1179, pp. 115-118).—In continuation of the author's investigations on Bryophyllum (E. S. R., 37, pp. 324, 325), additional information is given by which it is shown that the rate of geotropic bending of horizontally placed stems of B. calycinum, if an apical leaf is attached to the stem, increases with the mass of the leaf. The author believes that the phenomena of geotropism are due to the chemical mass action, probably of the common nutritive materials circulating in the sap, and they are apparently of the same nature as the growth of dormant buds, which is also due to a mass action of the same substances.

The effects of acids and salts on biocolloids, D. T. MacDougal and H. A. Spoehr (Science, n. ser., 46 (1917), No. 1185, pp. 269-272).—In continuation of investigations on what the authors term biocolloids (E. S. R., 37, p. 325), a report is given of the effects of various acids, alkalies, salts, and their various combinations in stimulating growth.

Anesthesia and respiration, A. R. C. Haas (Science, n. ser., 46 (1917), No. 1193, pp. 462-464).—A preliminary account is given of investigations on the effect of anesthetics upon respiration, from which the author concludes that when Laminaria is exposed to the action of anesthetics in sufficient concentration to produce any result there is an increase in respiration. This may be followed by a decrease if the reagent is sufficiently toxic, but no decrease was observed with low concentrations which were not toxic.

The measurement of light in some of its more important physiological aspects, D. T. MacDougal and H. A. Spoehr (Science, n. ser., 45 (1917), No 1172, pp. 616-618).—The results are given of a test of the photoelectric cell developed by Elster and Geitel, comparisons being made with the Smithsonian pyrheliometer.

The authors state that the sodium cell connected with a suitable portable galvanometer offers many advantages for the measurement of light intensities

in natural habitats and that the action of the photoelectric cell in light is more nearly parallel to that of the organism than that of any other lightmeasuring instruments hitherto available.

## FIELD CROPS.

Effect of fall irrigation on crop yields at Belle Fourche, S. Dak., F. D. FARRELL and B. Aune (U. S. Dept. Agr. Bul. 546 (1917), pp. 13, fig. 1).—The favorable results secured at Scottsbluff, Nebr. (E. S. R., 32, p. 36), with fall irrigation for spring-planted crops led to a repetition of the experiments under different soil conditions at the Belle Fourche Experiment Farm. The experiments were begun in 1913, and involved the use of oats, sugar beets, flax, potatoes, barley, corn, and wheat grown on duplicate check plats receiving the usual summer irrigation and on duplicate plats receiving in addition a fall irrigation. The results secured in 1914, 1915, and 1916 are reported and discussed.

The soil upon which these experiments were conducted is described as an extremely heavy clay, popularly known as "gumbo" and classified by the Bureau of Soils as Pierre clay. Mathews (E. S. R., 36, p. 210) reported that this soil would carry approximately 30 per cent moisture, about half of which would be available to crops, and that the wilting coefficient of the soil approximates 17 per cent. During the nine years 1908–1916, inclusive, the annual rainfall varied from 6.64 in. in 1911 to 21.02 in. in 1915, the mean being 14.05 in. The mean precipitation for the fall period (August to October, inclusive) for the 9-year period was 3.75 in. and for the winter period (November to March, inclusive) 2.15 in.

The average crop yields secured on the fall-irrigated plats and on the check plats are reported in tabular form and the summarized statement below given to show the probable errors of the average yields.

Summary of crop y	yields showing	the probable	errors of	the averages.
-------------------	----------------	--------------	-----------	---------------

Стор.	Unit of yield.	Fall-irriga	ated plats.	Check	Difference	
		Number of plats averaged.	Average yield per acre.	Number of plats averaged.	Average yield per acre.	in favor of fall irrigation.
Wheat	do	6	22. 1± 2. 2 61. 9± 5. 0 33. 9± 1. 5 13. 7± 1. 4 42. 2± 3. 3 8. 4± 1. 1 167. 0±23. 0	6 6 6 6	20. 1± 1. 4 67. 8± 6. 0 36. 1± 2. 5 15. 2± 0. 9 43. 9± 3. 1 9. 2± 1. 1 172. 0±19. 0	+2.0± 2. -5.9± 7. -2.2± 2. -1.5± 1. -1.7± 4. -0.8± 1. -5.0±30.

Since none of the differences in favor of fall irrigation was as great as the probable error, all were regarded as insignificant. The lower average yields of the fall-irrigated plats are attributed to the relatively low productivity of one of the two fall-irrigated series, the 3-year average yield of which was 16 per cent lower than that of the duplicate series, while the corresponding averages of the two check series were identical. This low production was thought to have been associated with a heavy infestation of gumbo weed, *Iva axillaris*, on the low-yielding series.

Soil moisture determinations made in the spring and early summer of each year are reported and the data tabulated for each year of the experiment. In 1914 the first two samplings showed more moisture in the first 3 ft. of the

fall-irrigated plats than in the corresponding depth of the check plats. No effect was noted beyond the third foot, the differences in the upper 3 ft. occurring at a time when all plats contained abundant moisture and disappearing before the end of June. No significant differences were found in 1915 or 1916.

The failure of fall irrigation to increase crop yields in these experiments appears to be attributable to the character of the soil. Being a heavy clay, absorption occurred only when the soil was dry, and was followed rapidly by expansion, which so compacted the soil that it became impervious and hindered the storage of water in the lower depths for the use of the crops.

Progress report, Substation No. 2, Troup, Tex., 1901-1914, W. S. HOTCHKISS (*Texas Sta. Bul. 209 (1917)*, pp. 1-13, 33 fig. 1).—Variety tests with cotton and corn for 1912-1914, inclusive, and fertilizer tests with sweet potatoes for 1907, 1908, and 1911 are noted, supplementing a previous report (E. S. R., 21, p. 536).

The average yields of the ten highest-yielding cotton varieties tested two or more times varied from 690 lbs. of seed cotton per acre for Half and Half to 756 lbs. for Texas Oak. Mebane, second with an average yield of 732 lbs. of seed cotton, is deemed superior to the other varieties tested because of its high yield of lint, averaging 38 per cent, and because of other desirable qualities.

In the corn variety tests Munson with 22.9 bu., Red Indian Chief with 22.1 bu., Strawberry with 20.5 bu., Oklahoma White Wonder with 20.4 bu., and Texseed Giant White with 19.1 bu. gave the highest average yields for two years.

In fertilizer tests with sweet potatoes the best results were obtained with acid phosphate and cottonseed meal, both when used singly and in combination, a mixture of the two being deemed advisable. An average increase of 30.3 bu. per acre for the three years of the test was attributed to acid phosphate and an increase of 33.3 bu. per acre to cottonseed meal. Potash is regarded as unnecessary on the soils on which these tests were conducted, while nitrate of soda, although giving good results, must compete with cottonseed meal as a source of nitrogen.

Report of the Bermuda Board of Agriculture, 1914–15, E. J. WORTLEY (Rpts. Bd. Agr. Bermuda, 1914–15, pp. 21–26, 27–32).—A general administrative report including a brief discussion of seed-potato improvement.

[Field crops work in Argentina], J. M. Huergo (Min. Agr. Argentina, Mem. Cong. Nac., 1914-15, pp. 42-45, 46, 50-53, 55, 56).—Brief reports are given of wheat improvement through selection, the importation and production of potatoes, alfalfa seed importations, the cotton industry, the production of rice, seed analyses, the classification of commercial seeds, the production of barley for brewing purposes, and tobacco production, for the year 1914-15.

[Field crops], P. Symeonides (Cyprus Agr. Jour., No. 44 (1917), pp. 974-978, pl. 1).—Fertilizer, variety, and cultural tests with wheat, barley, oats, rye, and canary seed are reported for the season of 1916. Further notes are given on "Sitarokrithi" (E. S. R., 34, p. 339), the so-called wheat-barley hybrid.

[Report of field crops work at the Bankipoor Agricultural Station, 1915–16], G. Sherrard (Rpt. Dept. Agr. Bihar and Orissa, 1915–16, pp. 43–49).—Fertilizer and cultural experiments with rice are reported for the year. An application of 4 tons of manure showed a net profit of \$6.18 per acre as compared with \$4.43 from an application of one-half that amount. Acid phosphate applied at the rate of 120 lbs. per acre showed a net profit of \$10.06, but when supplemented by 160 lbs. of ammonium sulphate of \$7.48.

Experiments are reported with gram (*Cicer arietinum*) sown broadcast in the standing rice and left to grow through the cold weather after the rice is removed.

Rate-of-seeding tests with rice indicated that seedings of 410 lbs. per acre of seed bed gave considerably higher yields than seedings of 615 lbs. Transplanting 8 seedlings per hole showed higher yields than 1, 2, or 4 seedlings per hole.

Variety and cultural tests with sugar cane are briefly noted. The yield of cane cultivated by the local method as compared with trenching was considerably higher for the former.

[Report of work with field crops at the Benares Agricultural Station], L. C. Sharma (Rpt. Benares Agr. Sta., United Provs. Agra and Oudh, 1916, pp. 5-14).—Reports are given on variety tests with sugar cane, corn, cotton, wheat, rice, barley, and gram, together with tests of sunn hemp and millet and a study of the effect of hot-weather cultivation on wheat yields.

The sugar-cane experiments included a comparison of thick and thin varieties, rate-of-seeding tests, fertilizer tests, and irrigation tests. Saretha, the highest yielding thin variety, gave 6,888 lbs. of gur (crude sugar) per acre, while Red Mauritius, the highest yielding thick cane, gave 8,448 lbs. per acre. The most satisfactory seeding rate was 20,000 cuttings per acre, with a yield of 52,808 lbs. of cane. Of various irrigations the highest yield of cane, 63,296 lbs. per acre, followed eight irrigations. The highest percentage of gur in the juice in the fertilizer tests was 19.1, obtained on the plat receiving 480 lbs. of ammonium sulphate per acre, while the highest yield of cane was obtained from the use of 180 lbs. of ammonium sulphate and 350 lbs. of acid phosphate, but this gave only 17.3 per cent of gur.

Irrigation experiments with wheat resulted in a yield of 2,044 lbs. of grain and 3,608 lbs. of straw per acre from three irrigations, as compared with 1,120 lbs. of grain and 1,640 lbs. of straw from one irrigation. Considerable gain was also realized from flushing the field before seeding. Hot-weather cultivation to preserve soil moisture was found to give increased yields of wheat over the ordinary methods, both with and without supplementary irrigations.

[Report of field crops work at the Cuttack Agricultural Station, 1915-16], D. R. Sethi (*Rpt. Dept. Agr. Bihar and Orissa*, 1915-16, pp. 56-63).—Manurial and variety tests with rice and cultural and seed selection tests are briefly reported as heretofore (E. S. R., 35, p. 31).

The results of fertilizer tests indicated that green manuring is the cheapest and most efficient system of fertilization, but owing to the fact that all the rice of this section is broadcasted the introduction of green manures is difficult. About 10 lbs. of daincha (Sesbania aculeata) were planted with the rice and the daincha plants plowed under through the unique system of "beushan" prevalent in this region. By this system the broadcasted fields are plowed and cross-plowed during July to thin the crop and as a means of cultivation. This plowing is immediately followed by a weeding which serves to cover up the uprooted daincha plants. The results of the first year of this experiment showed an increased yield of 146 lbs. of grain and 386 lbs. of straw per acre over the untreated field.

The transplanting of 2 or 3 seedlings 9 or 10 in. apart gave higher yields than the common practice of transplanting 10 or 12 seedlings 5 or 6 in. apart.

A comparison of transplanting rice with broadcasting showed an increased yield of 243 lbs. of grain and 420 lbs. of straw per acre for the former method. Cultivation of the paddy fields during the hot weather (April) showed an increased yield of 246 lbs. of grain and 169 lbs. of straw over monsoon (June) cultivation.

Variety tests with jute, peanuts, and peas are briefly reported.

[Report of field crops work at the Dumraon Agricultural Station, 1915–16], G. Sherrard (Rpt. Dept. Agr. Bihar and Orissa, 1915–16, pp. 52, 53).—A continuation of fertilizer and variety tests with rice as previously noted (E. S. R., 35, p. 32) is reported. An application of about 2 tons of manure per acre was followed by a net return of \$15.34 as compared with \$12.45 from an application of about 4 tons.

[Report of work with field crops at the Orai Experiment Station], B. C. Burt (Rpt. Agr. Sta. Orai, Jalaun [India], 1916, pp. 4-16).—Variety tests are reported with wheat, gram, millet, cotton, and pigeon peas. The Soharia variety of wheat is recommended for unirrigated regions, while Pusa 4 is recommended for all irrigated soils.

An average of 55.5 lbs. of wheat and 18.5 lbs. of gram per 0.1-acre plat was secured from a mixed seeding. Wheat in rotation after gram, however, yielded 107 lbs. per 0.1-acre plat, and gram after wheat 96 lbs.

An application of potassium nitrate equivalent to 25 lbs. of nitrogen per acre was followed by an increased wheat yield of only 10 lbs. of grain per acre, and a decrease of 350 lbs. of straw, as compared with the untreated check. The gram crop following gave an increased yield of 115 lbs. per acre on the fertilized plat.

[Report of work with field crops at the Partabgarh Agricultural Station], L. C. Sharma (Rpt. Partabgarh Agr. Sta. United Prov. Agra and Oudh, 1916, pp. 3-19).—Varietal, cultural, and fertilizer tests with rice, and varietal and cultural tests with sugar cane, peanuts, wheat, barley, gram, peas, and potatoes are noted.

An increased wheat yield of 633 lbs. of grain and 927 lbs. of straw per acre was obtained from plats cultivated in the ordinary way with three irrigations, as compared with the yields from hot-weather cultivation.

[Report of field crops work at the Ranchee Experiment Farm, 1915-16], A. C. Dobbs (*Rpt. Dept. Agr. Bihar and Orissa*, 1915-16 pp. 68-73).—This is the first annual report of experimental work at the Ranchee station and briefly outlines the projects being studied. Extensive fertilizer experiments with peanuts are in progress. The highest yield for the past year, 3,680 lbs. per acre, was obtained from an application of 160 lbs. of gypsum.

[Report of field crops work at Sabour Farm and Agricultural College, 1915-16], S. N. Sh. (Rpt. Dept. Agr. Bihar and Orissa, 1915-16, pp. 18-25, 34-37).—This reports the continuation of experiments previously noted (E. S. R., 35, p. 31).

Cultivation of the fallow during hot weather and the application of approximately four tons of manure per acre showed increased yields of grain over all other treatments.

Experiments with rice gave practically the same results as those of the previous year, with the following exceptions: The vitality of the seedlings appeared to be unaffected by thick planting in the seed bed; the wet seed-bed seedlings were inferior, due to the water-logged condition of the plats; on the manured plat the total yield was relatively small, due to lodging; and the difference between the "single" and "bunch" transplanting of seedlings in spacings 6 in. apart was very slight. Early transplanting (July 10) gave the best results. The green manuring of paddy lands has given good returns, which have been augmented by applications of lime and bone meal. Transplanting rice gave much higher yields of both grain and straw than sowing broadcast or dibbling.

Seedings of rahar (Cajanus indicus) in July gave higher yields than seedings in either May or June. Variety tests with rahar, wheat, and rice are reported.

[Report of field crops work at Sepaya Experiment Farm, 1915-16], M. M. MACKENZIE (Rpt. Dept. Agr. Bihar and Orissa, 1915-16, pp. 76-79, 82-87).— Experimental work with sugar cane, forage crops, and fertilizers is briefly outlined. Results of analyses of sugar-cane varieties grown at Sepaya are reported in tabular form.

Fodder crops of Western India, H. H. Mann (Dept. Agr. Bombay Bul. 77 (1916), pp. 142).—This is a compilation of available information relative to the cultivated fodder crops of Western India, showing the adaptation of each, method of cultivation, yield, and value of the fodder produced. The area under cultivated fodder crops in the Bombay Presidency is estimated to be about 124.920 acres.

Some wild fodder plants of the Bombay Presidency, W. Burns, R. K. Bhide, L. B. Kulkarni, and N. M. Hanmante (Dept. Agr. Bombay Bul. 78 (1916), pp. 24, pls. 34).—This bulletin is a compilation of available information relative to some of the wild grasses and leguminous plants used as forage in the Bombay Presidency, giving their vernacular names, habitat, life history, chemical composition, and feeding value. Thirty-four such plants are described and illustrated.

How to change the rotation system, G. Sorgia (Agr. Terra Lavoro, 6 (1917), No. 1, pp. 2-8).—The author describes in detail and illustrates with diagrams changing from a biennial rotation to a quadrennial rotation, based on Trifolium pratense, or to a septennial or octennial rotation, based on Medicago sativa. A method is also described for changing from a quadrennial system to an octennial one.

Experiments in meadow culture on peat bogs, V. A. Fominykh (Selsk. Khoz. i L@sov., 251 (1916), June, pp. 145-160).—This reports experiments in 1914 and 1915 in an effort to convert peat bogs into meadows. The different treatments resulted in the increased yields noted below: Harrowing alone, 56.8 per cent; harrowing combined with fertilizing, 300 per cent; seeding to grass after harrowing and fertilizing, 350 per cent—also procuring a change in the flora of the bog; plowing, fertilizing, and seeding to grass, 600 to 900 per cent.

Permanent pasture formation, A. W. Green (Jour. Agr. [New Zeal.], 14 (1917), No. 1, pp. 28-31).—This reports pasture-formation experiments in progress at Ruakura, New Zealand, to determine (1) the influence of temporary fillers on the permanent grasses and clovers which will ultimately constitute the permanent pasture, (2) the value of temporary fillers in reducing the weed content in permanent pastures, and (3) the comparative value of different fillers for early feed. The fillers included in the experiment were prairie grass, cape barley, Italian rye-grass, broad-leaved Essex rape, and thousand-headed kale.

The results to date indicate that rape is the most valuable plant of those tested, due to its habit of growth and resistance to cold. Sheep turned into pasture on the unfenced plats at first preferred the rye-grass, but soon left it for barley and rape. The kale plat was left until last. The highest total liveweight gain, 379 lbs., was obtained from a seeding of 2 lbs. of rape per acre, at the minimum cost for all fillers of 40 cts. The least gain in live weight, 175 lbs., was realized from a seeding of 25 lbs. of barley per acre, at a cost of 78 cts.

Grasses for pasture and hay in Texas, G. M. Garren (Texas Agr. Col. Ext. Serv. Bul. B-32 (1916), pp. 16, flys. 4).—A popular discussion of suitable hay and pasture grasses for Texas, with general recommendations for the establishment of meadows and pastures.

The selection of cereals in Italy, G. Patanè (Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, pp. 777-787; abs. in Jour. Heredity, 8 (1917), No. 3, p. 105).—Systematic plant breeding, principally with cereals, is being conducted at 10 centers in Italy, and the work, modeled after that of the Svalöf station, is reviewed in this article. Selection and hybridization form the principal features of the investigations, and include studies with wheat, rice, barley, oats, corn, rye, pulses, potatoes, pumpkins, tomatoes, alfalfa, and other crops.

A study of cleistogamy and parthenogenesis from the standpoint of genetics, especially with the Cruciferæ and Leguminosæ, is being made by U. Brizi at the Royal Agricultural College, at Milan. Cereals and Leguminosæ are also being bred on Mendelian lines.

The influence of chemical fertilizers upon the composition of the cereals (Agr. Mod. [Milan], 22 (1916), No. 24, pp. 284, 285).—This reports analyses of grain grown on different soil types in France and under varying fertilizer treatments to determine the effect of the fertilizer upon the composition of the grain. The fertilizers used were acid phosphate, sodium nitrate, muriate of potash, and manure.

In every case the weight of the grain was materially higher with the fertilizer treatment. A complete chemical fertilizer in each case resulted in a higher percentage of protein in the grain than on the untreated plat or the plats receiving only partial fertilization. Manure alone showed a slight increase in the protein content, except with corn, which showed a slight reduction. With manure supplemented by chemical fertilizers slightly increased percentages of protein were obtained. The percentage of phosphoric acid in the grain was increased under all fertilizer and manurial treatments. See also a previous note by Tretiakov (E. S. R., 34, p. 230).

Statistics on the production of cereals and legumes, 1916 (Estadistica de la Producción de Cereales y Leguminosas en el año 1916. Madrid: Govt., 1916, pp. 32).—Statistics are given on the acreage and production of wheat, barley, rye, oats, corn, chick-peas, vetch, field peas, beans, and other less important cereals and legumes in Spain for 1916. Brief observations are reported on the influence of meteorological conditions upon the cultivation and harvesting of cereals and legumes in each of 13 regions.

Growth of the root system of Medicago sativa, Shistovskij (Iuzh. Russ. Selsk. Khoz. Gaz., 17 (1915), No. 30, pp. 6, 7; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 8, pp. 1088, 1089).—Observations are reported on the development of the root system of M. sativa at different stages of growth.

The alfalfa was sown in Rotmistrov boxes in the open field and the roots examined by washing with water at the ages of 1, 2, 2.5, 3, 3.5, and 4 months. The results of these observations are reported in tabular form. The data include the length in centimeters of the aerial portion and roots and the horizontal extension of the roots, together with the root coefficient, which is the product of the length and the horizontal extension of the root.

The results indicate that the growth of the root system continues uninterruptedly from germination to fructification, but that growth is not uniform. At the age of 2.5 months the roots had attained a length of from 45 to 51 centi-

meters (17.7 to 20.1 in.), and in the following 2 weeks, which form the preflowering period and actual growing period itself, the root growth was very intense, attaining a length at the age of 3 months of from 103 to 110 centimeters. Such great fluctuations in root growth were not observed previous to or following this period, and the author believes this fact to be the essential point in his investigations.

These observations are said to confirm those of Rotmistrov, but better specify the process of root growth by establishing the period of most intense development.

The effect of phosphorus on alfalfa and alfalfa bacteria, H. W. TRUESDELL (Soil Sci., 3 (1917), No. 1, pp. 77-98, pls. 2).--Investigations are reported in an effort to discover the reason for the beneficial influence of phosphorus upon alfalfa and other legumes, as simple nutrition (shown by chemical analysis) is deemed insufficient to account for this phenomenon. The hypothesis is advanced that phosphorus fertilization may cause greater growth and activity of the root bacteria, resulting in greater nitrogen fixation and more rapid growth of the leguminous host. This theory has been tested experimentally in these investigations. The experiments fall into two parts, (1) those which treat of the influence of phosphorus upon the growth of the alfalfa organism (Bacillus radicicola) as shown by numerical counts, and (2) those which treat of the influence of phosphorus upon alfalfa as regards nodule formation, rate of growth, dry weight of plants, and percentage and absolute content of nitrogen. The secondary phosphates of potassium, sodium, and calcium were used in quantities sufficient to supply a phosphorus equivalent of 0.1, 0.02, and 0.002 per cent. The studies were made at the University of Wisconsin.

The treatment of pure cultures of B. radicicola from alfalfa with phosphates resulted in large increases in the number of organisms, varying with the character and solubility of the salt. The highest counts were obtained from treatments supplying a phosphorus equivalent of 0.02 per cent, and disodium phosphate gave the highest increase after seven days' incubation, with dipotassium phosphate next.

Pot culture experiments were conducted under greenhouse conditions to study the effect of dicalcium phosphate upon alfalfa. Alfalfa grown on unsterilized soil was inoculated, treated with phosphates and phosphorus plus nitrogen, and the results in nodule formation, dry weight, and percentage and absolute nitrogen content compared with all possible control combinations. Percentages of phosphorus of 0.005, 0.015, and 0.045, equivalent to field applications of 700, 2,100, and 6,300 lbs. per acre of rock phosphate, respectively, were employed, and urea equivalent to 0.014 per cent used as a nitrogenous fertilizer.

The results of phosphorus fertilization of alfalfa may be briefly summarized as follows: The seedlings made a much more rapid growth, and increased nodule formation, dry weight, and total nitrogen content was observed. The third cutting (much more representative of normal average conditions) showed not only an increase in total nitrogen, but also an increase in the percentage of nitrogen associated with the addition of phosphorus fertilizer.

The author concludes that the early increase noted in the growth of phosphorus-treated seedlings may be a result of nutrition of the plant and the stimulation frequently associated with cell reproduction and to the quickening of bacterial processes in the soil. The ultimate increases in growth resulting from phosphorus treatments may be due to increased infection with alfalfa organisms, increased growth and proliferation of the organism within the nodule, and consequently increased nitrogen fixation.

A bibliography of 26 articles comprising the literature cited is given at the end of the paper.

A semiannual cropping system for bean lands, G. W. Hendey (Univ. Cal. Jour. Agr., 4 (1917), No. 6, pp. 181, 182, fig. 1).—Recommendations are made concerning the utilization of bean land during the winter months for the production of certain hardy leguminous crops in California. Increases in the market prices for 1916 over those received before the war, amounting to from 21 per cent for horse beans to 150 per cent for Large White (Lady Washington) beans, has resulted in increased rentals and share leasings, necessitating more intensive cultural conditions.

A semiannual cropping system such as proposed presupposes a well-drained soil not subject to winter inundations but readily irrigable in October and May, as well as facilities for rapid handling of the crops in the field. The winter crop should be planted during October and harvested not later than May 15. The following crops are suggested and their market value briefly discussed: Horse beans, garbanzos, garden peas, field peas, and lentils.

Investigations on the mode of determining the germinating capacity in beet seed, E. Vitek (Ztschr. Zuckerindus. Böhmen., 40 (1916), No. 8, pp. 363-381; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 8, p. 1106).—Experiments are reported to determine whether blotting paper or sand give more accurate results in germination tests. In 1913, 26 samples of seed were compared, 77 per cent showing a higher germination on blotting paper than on sand, and 88 per cent giving a larger number of embryos on blotting paper than on sand. Analogous results were obtained in 1914.

Influence of very low temperatures on the germination capacity of beet seeds, J. Urban and E. Vitek (Ztschr. Zuckerindus. Böhmen., 40 (1916), No. 7, pp. 29–300; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 8, pp. 1105, 1106).—The authors report experiments with sugar beet seed to determine the influence of low temperature on germination. Samples of beet seed were exposed for 30 minutes at a temperature of —180° C., produced by the spontaneous evaporation of liquid air, and germinated with unexposed seed at a temperature varying from 20 to 30°. After 15 days 95 per cent of the unfrozen seed and 96 per cent of the frozen seed had germinated, indicating that the heaviest frosts do not impair the germinability of beet seeds having a normal water content.

To test the behavior of seed harvested in wet weather samples of seed containing approximately 20 per cent water were exposed to the same temperatures as above from 2 to 72 hours. The results indicated that the germinative capacity of the seed had been impaired by freezing, but that exposure for 72 hours had had no more effect than exposure for a shorter length of time.

Boiling buffalo clover seed, A. D. McNair (Science, n. ser., 45 (1917), No. 1157, pp. 220, 221).—The author reports tests with the seed of buffalo clover (Trifolium reflexum) in attempts to increase their germinability. The process of boiling the seed one minute as practised in the case of spotted bur clover (Medicago arabica) increased germination from 4 to 30 per cent. Experiments with bur clover conducted by the Alabama Experiment Station (E. S. R., 32, p. 829), in which the seed were soaked before boiling, led to similar tests with buffalo clover, with the following results as to percentages of germination: No treatment, 0; boiled 5 seconds, 53; boiled 30 seconds, 60; boiled 60 seconds, 60; soaked in cold water 12 hours, 0; soaked in cold water 12 hours and boiled 5 seconds, 47; soaked in cold water 12 hours and boiled 60 seconds, 93.

An interesting seed corn experiment, H. D. Hughes (Iowa Agr., 17 (1917), No. 9, pp. 424, 425, 448, ftg. 1).—This is a preliminary report on a test with prize-winning seed corn to determine whether such corn gives the highest production when planted in the field. Five hundred ears of corn were taken from the field in 1915 without any selection whatever, numbered, and scored by 25 judges. Later a portion of each ear was shelled and planted in separate field plats.

The results for the first year indicate that the ears receiving the highest scores were also the best ears from the standpoint of field production. The 50 best ears, as selected by a majority of the judges, averaged 5 bu. per acre better than the bulk of the ears.

Classification of American Upland cotton, D. E. EARLE and F. TAYLOB (U.S. Dept. Agr., Farmers' Bul. 802 (1917), pp. 28, figs. 15).—This is a revision of Farmers' Bulletin 591 (E. S. R., 31, p. 433), based on the Official Cotton Standards as established and promulgated by the Secretary of Agriculture under the United States Cotton Futures Act (E. S. R., 35, p. 693).

Cotton production in the Belgian Kongo, P. Janssens (Bul. Agr. Congo Belge, 7 (1916), No. 1-2, pp. 131-157, figs. 14).—A detailed review of the introduction and subsequent development of the cotton industry in the Belgian Kongo.

The development of cotton culture in French West Africa, J. Babois (Compt. Rend. Acad. Agr. France, 3 (1917), No. 5, pp. 141-148).—A general discussion of the possibilities of cotton production in the regions of Senegal and Niger.

The opportunities for cotton production in the French colonies, J. DYBOWSKI (Compt. Rend. Acad. Agr. France, 3 (1917), No. 5, pp. 149-155).—This is a general discussion directly bearing on the subject noted above. The economic necessity and desirability of developing the cotton industry in the territories of Senegal and the Sudan are emphasized.

Hemp culture in France, H. BLIN (Jour. Agr. Prat., n. ser., 30 (1917), No. 2, pp. 34-36, figs. 4).—A general discussion of the present status and future possibilities of hemp production in France.

The resources of Indo-China in oleaginous plants, Brenier (Compt. Rend. Acad. Agr. France, 3 (1917), No. 7, pp. 185-195).—A general discussion of the oil plants produced commercially in Indo-China, including brief specific notes on cotton, rubber, soy beans, castor oil, sesame, peanuts, coconuts, and other palms.

Growing potatoes under irrigation for profit, W. Stuart (Reclam. Rec. [U. S.], 8 (1917), No. 3, pp. 140-142, figs. 2).—The factors essential to the profitable production of potatoes under irrigation are enumerated and discussed as follows: Selection of a suitable soil type, deep plowing and thorough seed bed preparation, plentiful supply of available plant food, liberal use of good seed, good cultivation, intelligent application of irrigation water, protection against insect and fungus pests, careful harvesting and storing, and proper grading and intelligent marketing of the crop.

Notes and observations on the culture of ramie, L. NAUTEFEUILLE (Bul. Écon. Indochine, n. ser., 18 (1915), No. 115, pp. 649-718).—A comprehensive discussion of ramie and its production, compiled largely from available literature and augmented by some personal observations of the author. A brief history of the various agencies engaged in the exploitation of the industry is included.

Rice in Argentina, C. D. Gibola (An. Soc. Rural Argentina, 50 (1916), No 6, pp. 596-620, figs. 9).—Rice production and the extent of the industry in Argentina are discussed and brief descriptions given of the Kiuskú, Carolina, and Valencia varieties.

New rice varieties, B. MARCARELLI (Gior. Risicolt., 7 (1917), No. 1-2, pp. 4-10, figs. 2).—Two rice selections designated as Originario P. 7 and O. P. 6, developed by F. Sancio in the Province of Santhia from seed of Chinese origin, are described in detail. These strains are recommended as being of superior market quality. Data are presented in tabular form comparing them with the original.

Sweet clover (Melilotus), H. L. Fulmer (Ontario Dept. Agr. Bul. 235 (1916), pp. 32, figs. 10).—The value of sweet clover (Melilotus) as a pasture, hay, and soil improvement crop is discussed at some length.

A number of original analyses are presented showing (1) the composition of sweet clover at different stages of growth, (2) the yield and composition of sweet clover hay as compared with alfalfa, red clover, alsike, and timothy, (3) the dry matter and fertilizing constituents found in the tops (stems and leaves) and roots (in first foot of soil) and in the total crop at two different stages of growth and on two types of soil, (4) the composition of sweet clover and digestibility of its protein from two different types of soil and at six different stages of maturity, and (5) the total weight of nutrients and the amount of digestible protein furnished by one acre of sweet clover at six different stages of maturity.

Fertilizing the wheat crop, C. E. Thorne (Mo. Bul. Ohio Sta., 2 (1917), Nos. 7, pp. 215-218, fig. 1; 8, pp. 251-253).—The results of experiments previously reported with acid phosphate, steamed bonemeal, and raw rock phosphate used with fresh stable manure as fertilizers for wheat are briefly noted to illustrate the value of phosphatic materials in increasing wheat production, and the value of fresh manure reenforced with a phosphorus carrier as a substitute for high-priced commercial carriers of nitrogen and potash. The relative importance of the phosphorus was shown by an increase valued at only \$11 per acre where phosphorus was omitted, the nitrogen and potassium carriers remaining unchanged, as compared with an increase amounting to \$39 upon the addition of acid phosphate valued at \$2.60.

Acid phosphate versus raw phosphate rock—relative prices will determine the choice for wheat this fall, C. G. Williams (Mo. Bul. Ohio Sta., 2 (1917), No. 8, pp. 249, 250).—The relative value of raw rock phosphate and acid phosphate for wheat is briefly considered in the light of experiments previously noted (E. S. R., 31, p. 217). The more profitable return in these tests was obtained from the investment in acid phosphate.

Adzuki beans and jimson weeds.—Favorable class material for illustrating the ratio of Mendel's law, A. F. Blakeslee and B. T. Avery (Jour. Heredity, 8 (1917), No. 3, pp. 125-131, figs. 4).—The authors discuss the adaptability of the adzuki bean (Phaseolus mungo) and the jimson weed (Datura stramonium and D. tatula) as material for illustrative purposes in classes in genetics.

The closeness of the ratios to expectations in the jimson weed is indicated in summarized data on pigmentation and capsule characters obtained in connection with other studies. A study of variability in jimson weed is being made by the senior author.

The Canadian Seed Growers' Association and its work (Ottawa: Association, pp. 8, figs. 2).—This is a brief outline of the organization, purpose, and methods of procedure of the Canadian Seed Growers' Association, together with brief descriptions of some of the more important varieties of wheat, oats, barley, and peas distributed.

A method for determining the impurity of cereals caused by the seed of Agrostemma githago, A. AINATA (JANATA) (Iuzh. Russ. Selsk. Khoz. Gaz., 17 (1915), No. 47, pp. 6-8; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 9, pp. 1272, 1273).—A total of 1,820 seeds of

A. githago, taken from samples of oats, barley, rye, and wheat collected in 11 districts of the Government of Kharkov, were weighed, and the average weight of one seed found to be 0.0101 gm. The weight of individual seeds fluctuated between 0.0128 gm. and 0.0056 gm.

## HORTICULTURE.

[Report on horticultural investigations at the Troup substation], W. S. HOTCHKISS (Texas Sta. Bul. 209 (1917), pp. 13-33, figs. 3).—Data are given on fertilizer experiments conducted with watermelons in 1904 and 1906, and with strawberries in 1907, 1908, and 1909. As a result of these tests mixtures of acid phosphate and cottonseed meal are advised, both for watermelons and strawberries.

Sixty-eight varieties of peaches and 105 varieties of grapes tested at the substation are here described, and varieties recommended both for market and home use.

Report of the horticultural experiment station, Vineland station, Ontario, 1906-1915 (Rpt. Hort. Expt. Sta., Vineland, Ont., 1906-1915, pp. 79, ftgs. 42).—This report comprises as a whole a record of the work of the Vineland station, Ontario, from the time of its establishment in 1906 up to October 31, 1915.

Most of the experimental work has been started in different years since 1912 and consists of plant breeding, variety tests, and various cultural investigations with orchard and small fruits and vegetables. A record is given of all crosses made with fruits and vegetables, together with lists of varieties being tested and the results to date of the more important cultural experiments.

Plant breeding at the horticultural experiment station, Vineland, E. F. PALMER (Canad. Hort., 40 (1917), No. 11, pp. 286, 287, figs. 3).—A summarized record of breeding experiments with fruits at the Vineland station, Ontario, in 1916 and 1917.

[Vegetables at Wisley, 1915-16] (Jour. Roy. Hort. Soc., 42 (1917), No. 2-3, pp. 400-411).—Notes are given on a number of varieties of cabbage tested at Wisley in 1915 and 1916.

Rules and regulations promulgated under authority of the Federal Standard-Barrel Law (U. S. Dept. Com., Bur. Standards Circ. 71 (1917), pp. 8).—Rules and regulations are given under the act previously described (E. S. R., 32, p. 499).

[Directions for the control of insect pests and diseases] (Utah State Hort. Com. Bul. 1, rev. (1916), pp. 64).—This bulletin briefly describes the more important insect pests and diseases of fruits and vegetables, and gives directions for their control. The text of the horticultural laws of Utah, regulations of the State Horticultural Commission, and the law governing the marking of closed packages of fruit are also given.

Dusting for tender fruits and apples, L. CAESAR (Ann. Rpt. Fruit Growers' Assoc. Ontario, 48 (1916), pp. 47-51).—A comparative test of dust and liquid sprays was carried out in 1916 on apples, plums, sweet cherries, peaches, and grapes in various orchards in Ontario.

Although the results were somewhat in favor of the dust method in this experiment, less favorable results from dusting were reported by others in Ontario and in New York State. Hence it is recommended that growers do not purchase dusting machines until further comparative studies have been made

Dusting as a substitute for spraying.—History and progress, H. H. WHETZEL (Ann. Rpt. Fruit Growers' Assoc. Ontario, 48 (1916), pp. 37-41).—This is

largely a review of studies conducted at the New York Cornell Experiment Station (E. S. R., 34, p. 738), including a summary of results secured in cooperative demonstration tests in New York apple orchards in 1916. Although the results of dusting as compared with spraying were less favorable in these cooperative tests than in the experimental work, the author is of the opinion that the failure was due to inexperience in the dusting method, use of improperly prepared mixtures, and poor dusting machinery rather than to the practice of dusting itself.

New creations in fruits, N. E. Hansen (Minn. Hort., 45 (1917), No. 12, pp. 464-469, figs. 4).—This paper comprises a brief statement of progress being made in the author's work of breeding hardy fruits (E. S. R., 37, p. 142).

A number of plums recently sent out for trial are described. Of a large number of cherries tested at the South Dakota Experiment Station one variety, selected from a number of imported seedlings and which has been named Moscow, has been found to be both productive and perfectly hardy and was distributed for testing in the spring of 1917.

A list of the most desirable varieties of most kinds of fruits (London: Roy. Hort. Soc., 1916, pp. 190).—The list herein given was prepared by the fruit committee of the Royal Horticultural Society of England as a result of inquiries sent out to growers throughout the United Kingdom. A series of subsidiary lists, prepared by a number of gardeners living in various parts of the United Kingdom, is given of varieties which they consider most suitable for their various geographical divisions.

Grass mulch.—A practical system of orchard management, J. H. GOURLEY (Ann. Rpt. Vt. State Hort. Soc., 14 (1916), pp. 36-41).—In connection with orchard management studies being conducted at the New Hampshire Experiment Station (E. S. R., 36, p. 724), a grass mulch experiment was recently established on a small orchard. Various fertilizers were applied to the different plats. Data are here given showing the results secured in 1916.

The average yield of apples from the check rows was 10.5 bbls., from the nitrogen rows 23.5 bbls., and the average from the rows fertilized with potash, basic slag, or phosphate, but not including nitrogen, about 11 bbls. Although the color of the apples was not so good on the nitrogen plat the increase in production far outweighed the color factor and all the apples were sold at the same price. The results in general indicate that nitrogen is the only fertilizer to yield a profit, and that in this orchard at least the mulch system would be far from efficient unless supplemented with nitrogen.

Orchard cover crops for the Moutere Hills, W. C. Hyde (Jour. Agr. [New Zeal.], 13 (1916), No. 6, pp. 472-477, figs. 7).—The author outlines cooperative experiments being conducted in the Moutere district of New Zealand to determine the leguminous crop best suited for green manuring purposes in the young orchards of that locality. The experiments also included trials of various fertilizer combinations.

The crops tested were crimson clover, common vetch, white lupine, yellow lupine, white mustard, serradella, and partridge peas. The best results were secured with white lupine and white mustard, together with an application of 1 cwt. per acre each of blood and bone, acid phosphate, and muriate of potash.

Important factors in the successful cold storage of apples, H. S. Bird (Rpt. Proc. Mont. State Hort. Soc., 19 (1916), pp. \$4-36).—A brief discussion of the factors essential to the successful cold storage of apples, including some experimental data illustrating the damage by scald and decay due to storing immature fruit, over-mature fruit, and to delay in storage after picking the fruit.

The history and development of the red currant, E. A. BUNYARD (Jour. Roy. Hort. Soc., 42 (1917), No. 2-3, pp. 260-270, pls. 6).—A paper on this sub-

ject read before the Royal Horticultural Society, London, on September 12, 1916.

A bibliography of cited literature is appended.

Viticulture, P. PACOTTET (Viticulture. Paris: J. B. Baillière & Sons, 1917, 3. ed., rev. and enl., pp. 554, figs. 217).—This is one of the volumes of the Encyclopédie Agricole, published under the direction of G. Wery.

The introductory chapter contains a brief survey of the genus Vitis. Succeeding chapters deal with the anatomy and physiology of the grape, factors influencing quality and production, the viticultural geography of France and foreign countries, the details of grape growing, ampelography and reconstitution of vineyards, and the maladies and enemies of the grape.

Citrus culture in Japan, China, and Formosa, C. P. CLAUSEN (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 10, pp. 379-383, figs. 3).—A brief account of cultural methods employed in Japan, China, and Formosa.

Some abnormal water relations in citrus trees of the arid Southwest and their possible significance, R. W. Hodson (Univ. Cal. Pubs. Agr. Sci., 3 (1917), No. 3, pp. 37-54, pl. 1, figs. 2).—This paper deals with one phase of the investigation of a so-called physiological disease, June drop of the Washington navel orange.

As a result of observations and experiments, here noted, it was found that an abnormal water relation obtains periodically in citrus foliage and in the young fruits during the hot growing season in the dry interior valleys of California and Arizona. A diurnal decrease in water content of the fruits occurs during the afternoon and is accompanied by a considerable increase in the water deficit of the leaves. "Negative pressures of considerable magnitude are found in the water columns of citrus trees under these climatic conditions. These attain their maximum during the afternoon. The dropping of the fruits appears to be most severe where the above-mentioned water relations are most abnormal. Inasmuch as in the case of certain other plants the abscission of young fruits has been shown to be due to abnormal water relations it is suggested that such may be the case here."

Optimum moisture conditions for young lemon trees on a loam soil, L. W. FOWLER and C. B. LIPMAN (Univ. Cal. Pubs. Agr. Sci., 3 (1917), No. 2, pp. 25-36, pls. 3, fig. 1).—In the experiment here described, which was conducted at the Limoneira Ranch, Santa Paula, Cal., studies were made of the optimum moisture content of a rather heavy loam soil for young Lisbon lemon trees grown in cylinders. The data obtained in the course of the first two years of the work are summarized as follows:

"A moisture percentage of 20 based on the dry weight of the soil has produced the tallest trees. Trees grown with 16 and 18 per cent of moisture, while not as tall as those grown with 20 per cent of soil moisture, show better color and more vigor. The differences are not very marked, however.

"The foregoing facts seem to show that the range of optimum or nearly optimum moisture percentages for the soil and plant in question is a relatively wide one. Much more visible damage results to the young lemon trees from moisture percentages in excess of the optimum than from those below the optimum. Every successive increment of moisture beyond the optimum is accompanied by a sharp depression in growth, color, and general vigor of the trees. Every successive decrement of moisture from the optimum shows only a relatively slight depression in growth.

"The theoretical wilting point and the moisture equivalent for the soil studied are in close accord, respectively, with the actual wilting point as determined in the soil of the orchard and the optimum moisture content as determined in the experiment discussed above."

Orange culture, A. DE MAZIÈRES (La Culture des Orangers. Paris: J. B. Baillière & Sons, 1917, pp. 96, figs. 28).—A small treatise on the planting, culture, harvesting, and marketing of oranges.

The fig in Texas, A. T. Potts (Texas Sta. Bul. 208 (1917), pp. 41, figs. 13).—A treatise on fig growing, with special reference to the development of the industry in Texas. Information is given relative to the climatic requirements of the fig, propagation, varieties, soil and its preparation, planting, culture, pruning, fertilizers, insects and diseases, splitting and souring, harvesting and marketing fresh fruit, preserving and drying, and the Smyrna fig and caprification.

The subject matter is based upon observations made in Texas and upon the industry as developed in other sections of the United States.

The guavas of the Hawaiian Islands, V. MacCaughey (Bul. Torrey Bot. Club, 44 (1917), No. 11, pp. 513-524).—A descriptive account of the species and forms of guavas established in the Hawaiian Islands.

The pollination of the mango, W. Popenoe (U. S. Dept. Agr. Bul. 542 (1917), pp. 20, pls. 4, fig. 1).—This bulletin reports pollination studies conducted at Miami, Fla., during 1915 and 1916 to throw some light on the failure of many of the best imported varieties of mangoes to fruit satisfactorily in Florida. The flower structure, pollen, process of pollination, production of fruit, and flowering habits of the mango are considered in detail.

The author's experimental work shows that the mango requires pollination for the production of fruit and is benefited by cross-pollination, though normally self-fertile. The exclusion of insects is detrimental to pollination, but even in the presence of insects a large proportion of the stigmas are unpollinated and comparatively few stigmas receive more than one or two grains of pollen. Hand pollination with an abundance of pollen failed to improve fruit production.

The failure to set fruit is not deemed to be due to any morphological defect in the pollen or to defects in the mechanism of pollination, hence it is concluded that the problem is a physiological one connected with nutritional conditions, as influenced by changes in soil moisture and food supply, principally the former. Experiments have been undertaken in cooperation with E. J. Kraus, of the Oregon Experiment Station, who is working with pomaceous fruits, to test the practicability of inducing the formation of flower buds through ringing, girdling, and banding the limbs with wire.

Some results with oil palm (Elæis guineensis), W. M. VAN HELTEN (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Cultuurtuin, No. 8 (1917), pp. 22, pl. 1).—Data are given showing the yields of nuts and oil secured in 1916 from oil palms growing in the Buitenzorg Gardens and vicinity. These yields are compared with yields secured in other countries. Notes are also given on methods of propagation and planting the oil palm, based upon tests conducted at Buitenzorg and elsewhere.

Coffee in Abyssinia, A. SPALLETTA (Agr. Colon. [Italy], 11 (1917), Nos. 1, pp. 70-88; 2, pp. 111-132, pls. 2; 3, pp. 196-222, pl. 1; 4, pp. 284-297).—An account of the coffee industry in Abyssinia, including a discussion of varieties, soil, and climate, cultural details, harvesting and preparation for market, commerce, transportation, and the future of the industry. A bibliography of related literature is appended.

A review of coffee plantings in the Buitenzorg experimental garden, C. J. J. VAN HALL and W. M. VAN HELTEN (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Culturtuin, No. 7 (1917), pp. 50, pls. 8).—Notes are given on the character and condition of plantings of various species, hybrids, and varieties of coffee under observation at Buitenzorg.

The germination and selection of tea seed, C. Bernard (Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 1 (1917), pp. 1-12, pl. 1).—A translation of an ar-

ticle dealing with the author's experiments on the germination and selection of tea seed (E. S. R., 30, p. 742; 35, p. 745).

[Flowers at Wisley, 1916] (Jour. Roy. Hort. Soc., 42 (1917), No. 2-3, pp. 412-429).—This comprises notes on variety tests of a number of different flowers conducted at Wisley in 1916.

Daffodil developments, J. Jacob (Jour. Roy. Hort. Soc., 42 (1917), No. 2-3, pp. 229-235).—A brief historical review of the work of improvement in daffodils.

The practical book of outdoor rose growing for the home garden, G. C. Thomas, Jr. (Philadelphia and London: J. B. Lippincott Co., 1917, 4. ed., pp. 215, pls. 120).—The present edition of this work (E. S. R., 32, p. 339) has been largely rewritten to include improved cultural practices and revised lists of the best varieties of dwarf and climbing roses based on recent tests.

Observations on tulips, A. B. Stout (Jour. Hort. Soc. N. Y., 2 (1917), No. 14, pp. 201-206, pls. 2).—Experiments conducted at the New York Botanical Garden indicate that it is difficult to attribute "blindness" of tulips to any one cause. Cultural tests made with two varieties prove that blind tulips may bloom excellently in the following year. Hence, they are not necessarily "rundown" or "run-out" bulbs. Different varieties have performed differently with respect to blindness under quite identical conditions of treatment and climate.

Data are also given showing the performance of sister bulbs of different sizes, and especially those of the smaller size, with respect to blooming, blindness, and scaling. Further observations are to be made on the performance of small bulbs which produced flowers in the experiment.

Report of the tulip nomenclature committee, 1914-15, Bowles et al. (London: Roy. Hort. Soc., 1917, pp. 164, pls. 22).—A report of the tulip nomenclature committee of the Royal Horticultural Society of England, in which is presented a scheme for the classification of garden tulips, descriptions of garden tulips as tested at Wisley, descriptions of new cottage tulips, list of synonyms, alphabetical list of tulip names, and a bibliography on tulips.

#### FORESTRY.

The development of forest law in America, J. P. Kinney (New York: John Wiley & Sons, Inc., 1917, pp. XVIII+254+XXI).—A historical presentation of the successive enactments, by the legislatures of the 48 States of the American Union and by the Federal Congress, directed to the conservation and administration of forest resources.

Recent forestry propaganda in the Philippines, F. Sherfesee (Jour. Forestry, 15 (1917), No. 6. pp. 740-756).—The author reviews the forest propaganda in the Philippines and sketches the present attitude of the Filipinos with respect to forest activities.

Practical reforestation, H. S. Graves (*Proc. Cut-Over Land Conf. South, 1917, pp. 15-23*).—In this paper the author briefly summarizes the present status of cut-over pine land areas in the South and urges cooperation between public and private agencies in developing methods for the systematic use of these lands for grazing, agriculture, and forestry.

How Louisiana is solving the reforestation problem, M. L. ALEXANDER (*Proc. Cut-Over Land Conf. South, 1917, pp. 169-172*).—A brief summary of reforesting operations being conducted under the direction of the Department of Conservation of Louisiana.

An improved transplanting lath, J. LYFORD-PIKE (Trans. Roy. Scot. Arbor. Soc., 31 (1917), pt. 2, pp. 160, 161, pl. 1).—A lath or board designed for transplanting a large number of tree seedlings or other plants in one operation is described and illustrated.

The preservation of leafy twigs of the beech, L. A. Boodle (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 6 (1917), pp. 220-231).—Experiments reported by the author indicate that leafy twigs of the common beech may be preserved for several months with very little wilting by cutting the twigs when the leaves are still green and placing the stems in a solution of calcium chlorid for about a week. The best results were secured by using solutions with specific gravities of 1.4 and 1.2. The lower ends of the twigs were trimmed every day or two to present freshly cut surfaces to the liquid and the twigs were exposed to direct sun for several hours during the treatment.

The importance of plantation margins, A. Murray (*Trans. Roy. Scot. Arbor. Soc.*, 31 (1917), pt. 2, pp. 156-159).—A short paper on the selection of species for and the subsequent management of forest plantation margins or shelter belts.

Trees for nonirrigated regions in eastern Colorado, W. J. MORRILL (Colo. Agr. Col. Ext. Serv. Bul., 1. ser., No. 123 (1917), pp. 20, figs. 6).—A descriptive list of trees and shrubs, including notes on their general behavior in eastern Colorado, is given, together with suggestions on tree planting.

Forest succession and rate of growth in sphagnum bogs, G. B. Rigg (Jour. Forestry, 15 (1917), No. 6, pp. 726-739, figs. 3).—A discussion of forest succession and rate of growth in six bogs of the Puget Sound region and four in Alaska, based on field observations conducted for several years.

Aspen as a permanent forest type, J. M. Fetherolf (Jour. Forestry, 15 (1917), No. 6, pp. 757-760).—In this paper the author brings out the more permanent features of aspen as a type, based on its behavior in habitats like the semiarid intermountain region.

The pitch pine, L. PICCIOLI (Ann. R. Ist. Sup. Forestale Naz. Firenze, 2 (1916-17), pp. 401-431, pls. 4, figs. 6).—An account of the various species of pine commonly known as pitch pine with reference to their distribution, anatomical characters, technical properties, and culture in Europe. The account is prepared with special reference to the selection of species adapted to Italian silviculture.

Notes on white pine 4-year transplants, S. N. Spring (Jour. Forestry, 15 (1917), No. 6, pp. 761, 762).—A growth record is given of white pine seedlings grown from three seed beds which were sown broadcast with different quantities of seed.

The density of stand and rate of growth of Arizona yellow pine as influenced by climatic conditions, F. Shreve (Jour. Forestry, 15 (1917), No. 6, pp. 695-707, figs. 6).—A contribution to our knowledge relative to the influence of climate on tree growth, based on observations and measurements made in the Santa Catalina Mountains in southern Arizona. Data are given showing the differences in population of the Arizona yellow pine at different altitudes, the differences in the character of the populations, and the differences or similarities in the rate of growth at the several elevations.

Probable error in field experimentation with Hevea, O. F. BISHOP, J. GRANTHAM, and M. D. KNAPP (India-Rubber Jour., 54 (1917), No. 15, pp. 13-16, 19-22, fig. 1).—A review of recent literature on the subject, including actual records of experiments in Sumatra showing variations that may occur among carefully chosen experimental plats and the need of applying probable error methods. An example is given of the application of the probable error method to a series of 26 tapping experiments which were carried on in triplicate.

Seed selection in the cultivation of Hevea brasiliensis, T. Petch (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 3 (1917), pp. 118-120).—A brief ac-

count is given of seed selection studies of Hevea conducted under the direction of the Ceylon Department of Agriculture.

The effects of tapping and wintering on the storage of plant food in Hevea, A. A. L. Rutgebs (Arch. Rubbercult. Nederland. Indië, 1 (1917), No. 2; Meded. Alg. Proefstat. Alg. Ver. Rubberplanters Oostkust Sumatra, Rubber Ser., No. 1-2 (1917), pp. 1-8, pls. 3).—A brief summary of investigations on this subject conducted by Campbell and Bateson (E. S. R., 33, p. 543; 34, pp. 47, 240, 346). These authors are of the opinion that tapping should be stopped from the moment the new leaves are coming out until a week after the crown is full-grown. The reviewer, on the other hand, concludes that wintering takes only one-sixth of the starch reserve at the most, and since tapping takes practically none from a physiological point of view there is no reason to stop tapping during the winter.

Rubber soils in Fiji, C. H. WBIGHT (Dept. Agr. Fiji Pamphlet 26 (1917), pp. 2).—This pamphlet contains directions for distinguishing soils adapted for rubber growing in Fiji.

Annual progress report on forest administration in the Presidency of Bengal for the year 1915-16, H. A. Farbington (Rpt. Forest Admin. Bengal, 1915-16, pp. II+51+5).—This is the usual report relative to the administration and management of the State forests of the Presidency of Bengal, including a financial statement for the year 1915-16. All important data relative to alterations in areas, forest surveys, working plans, forest protection, miscellaneous work, yields, revenues, expenditures, etc., are appended in tabular form.

Forest Service stumpage appraisals, J. W. GIRARD (Jour. Forestry, 15 (1917), No. 6, pp. 708-725).—This article deals with the appraisal of saw-log material and the logging methods employed in Montana, Idaho, and northern Washington.

Marketing farm woodlot products in Maine, G. N. Lamb (Univ. Maine Ext. Bul. 113 (1917), pp. 38, figs. 5).—This bulletin, which is published in cooperation with the Forest Service of the U. S. Department of Agriculture, discusses the woodlot situation in Maine; the common woodlot trees, including their growth, uses, and properties; estimating standing timber and saw logs; methods of selling timber; and the preparation and marketing of woodlot products destined for various industries.

Crossties purchased and treated in 1915, A. M. McCreight (U. S. Dept. Agr. Bul. 549 (1917), pp. 8).—A statistical review for the year 1915. The total number of crossties bought by all classes of producers was approximately 121,-402,611. Treating plants reported a total of 37,085,585 crossties treated in 1915.

#### DISEASES OF PLANTS.

Common and scientific names of plant diseases, M. B. WAITE (Abs. in Phytopathology, 7 (1917), No. 1, p. 60).—The author makes a plea for definite common names for plant diseases which can attain proper status in discussions, literature, dictionaries, quarantine regulations, laws, and legal proceedings.

[Plant diseases in British Guiana], C. K. BANCROFT (Rpt. Dept. Sci. and Agr. Brit. Guiana, 1914-15, App. 2, pp. 7-10).—Besides a summary of organisms causing diseases of cultivated crops in the colony during three years, brief details are given of the South American leaf disease of Hevea (Fusicladium macrosporum); the dry disease (Marasmius sacchari) and the ring spot (Leptosphæria sacchari) of sugar cane; the fruit disease of mango and breadfruit (Glæosporium mangiferæ); witches' broom of cacao; a disease of leaves and fruit of the coffee plant due to a Colletotrichum (C. coffeæ?); the bacterial disease of plantains; blast of rice (Piricularia oryzæ); collar rot of lime;

citrus knot; bud rot of coconut palm; root disease (Fomes semitostus) of Hevea; rose mildew (Sphærotheca pannosa); black blight (Dimerosporium mangiferum) of Hibiscus, Ixora, Barbados cherry, and Bougainvillea, besides several other plants; and a bacterial disease of orchids.

Scolecotrichum graminis on timothy, orchard grass, and other grasses, A. G. Johnson and C. W. Hungebford (Abs. in Phytopathology, 7 (1917), No. 1, p. 69).—The authors report having observed S. graminis on timothy and orchard grass at various points from Wisconsin to the Pacific coast. The fungus is said to cause a serious disease of these hosts, especially in Wisconsin. A number of other species of grass are reported as hosts of the fungus, and observations at Madison, Wis., are considered to show that it overwinters readily in tufts of orchard grass and timothy.

Bacteria of barley blight seed-borne, L. R. Jones, A. G. Johnson, and C. S. Reddy (Abs. in Phytopathology, 7 (1917), No. 1, p. 69).—In continuation of a previous study of a bacterial blight of barley (E. S. R., 35, p. 845), the authors have given special attention to the dissemination of the disease over long distances, and they conclude that the organism may be carried with the seed grain and remain viable after at least two years of dormancy. Preliminary experiments are said to indicate that the organism may be destroyed by seed disinfection.

Corn disease caused by Phyllachora graminis, Noba E. Dalbey (Phytopathology, 7 (1917), No. 1, pp. 55, 56, fig. 1).—A brief account is given of observations on the fungus P. graminis on leaves of maize collected in Porto Rico. A detailed description of the disease and fungus is to be given in a subsequent publication.

Smut diseases of wheat, W. B. Mercer (Jour. Bd. Agr. [London], 23 (1916), No. 7, pp. 633-643, figs. 2).—Along with a brief discussion of several smuts of economic cereals, the author gives brief notes of studies, to be published elsewhere in greater detail, regarding the life history of Ustilago tritici, the cause of loose smut of wheat.

The fungus is said to be capable of entering the young grain, but not the seedling. The chlamydospores germinate inside the flower and the tube penetrates the immature grain, giving rise to a small amount of mycelium in the embryo and the starchy endosperm, the grain developing in spite of this fact. When the infected grains are sown, the fungus grows with the young plant in a way similar to that of the bunt fungus. When the head begins to form, the mycelium begins to grow more rapidly, branches profusely, and forms a large number of spores, which are at first held together by a gelatinous substance enclosed in a thin membrane which usually ruptures as the ear emerges. Unless these spores thus freed reach a flower they become harmless, probably in a few days.

The control measures tried up to the present time are outlined. The fungus can not be reached with chemical fungicides. The method of picking out the smutted heads from the standing crops, while fairly effective, is not practicable on a large scale. Selection of seed on the basis of size or weight is ineffective. Steam has given some fair results, but is not considered safe as a seed treatment. Forcing hot water through the seed grain is impracticable. Hot-air kilns do not heat the grain evenly. Rolling the grain in heated drums has met with a measure of success. The treatment found most effective is to soak the wheat in water at a temperature of 25 to 30° C. (77 to 86° F.) for four hours and then for 10 minutes at 52 to 54° C. (125.6 to 129.2° F.), this treatment destroying the fungus with a comparatively slight lowering of germinability.

Tylenchus tritici on wheat, L. P. Byars (*Phytopathology*, 7 (1917), No. 1, pp. 56, 57).—The author reports having determined the presence of the nematode T. tritici in wheat heads transmitted through the Office of Cereal Investigations of this Department from Nanking, China. The data presented are offered in order that measures can be taken to prevent the introduction of this parasite with wheat importations from infested countries.

Bean diseases in New York State in 1916, W. H. Burkholder (Abs. in Phytopathology, 7 (1917), No. 1, p. 61).—In continuation of a report on diseases of the field bean (E. S. R., 36, p. 248), the author states that the most serious disease is due to a species of Fusarium which is considered nearly identical with F. martii. This causes a dry root rot of the bean plant. The organism is said to winter over in manure where bean straw has been used as feed, and there is evidence that it may live for several years in the soil. All varieties of beans are about equally susceptible to the attack of this fungus, although certain undesirable types of the white marrow are very resistant, and a few individuals of these have been selected for breeding experiments.

A blight, caused by *Bacterium phaseoli*, and mosaic are said to have been rather conspicuous in the bean crop of 1916, while the anthracnose which was destructive in 1915 caused little damage in the following year. The author claims that there is some indication that *B. phaseoli* causes a stem girdling.

Bacterial diseases of celery, W. S. Krout (Abs. in Phytopathology, 7 (1917), No. 1, p. 64).—The author gives a description of a crown rot of celery which appears to be caused by a bacterium working simultaneously with a species of Fusarium, a crown rot wilt, and a bacterial heart wilt.

Wintering of Septoria petroselina apii, W. S. Krout (Abs. in Phytopathology, 7, (1917), No. 1, p. 65).—As a result of the author's studies, it is believed that the above fungus is not carried on celery seed but in manures containing diseased, decomposed plants and probably by other methods. Laboratory investigations have shown that heating celery seed at 50° C. (122° F.) for half an hour will eliminate all chances, if there are any, of the disease being disseminated through the seed and pedicles.

Dissemination of the organism of cucumber anthracnose, M. W. GARDNER (Abs. in Phytopathology, 7 (1917), No. 1, pp. 62, 63).—The author presents evidence indicating that this disease of cucumbers is introduced by the seed and that subsequent spread is largely due to surface drainage.

Do the bacteria of angular leaf spot of cucumber overwinter on the seed? E. CARSNEB (Abs. in Phytopathology, 7 (1917), No. 1, pp. 61, 62).—The fact that angular leaf spot appeared only on seedlings in six fields planted with seed from the same source and not in other fields in the vicinity is considered by the author as a basis for the hypothesis that the causal organism is seed-borne.

Preliminary notes on a new leaf spot of cucumbers, G. A. OSNER (Abs. in Phytopathology, 7 (1917), No. 1, p. 62).—During the seasons of 1915 and 1916, the author's attention was called to a peculiar leaf spot on cucumbers which was causing more or less damage in a number of fields. The spots for the most part were small and limited by the veins of the leaf. The disease is claimed to be due to a fungus, the exact generic position of which has not yet been determined.

Virulence of different strains of Cladosporium cucumerinum, W. W. GILBERT (Abs. in Phytopathology, 7 (1917), No. 1, p. 62).—As a result of investigations the author has found that different strains of C. cucumerinum vary widely in their ability to infect cucumber plants, some virulent strains killing the plants in two to four days, while nonvirulent strains failed to produce infection. Similar results were obtained from the inoculation of young cucumbers in moist chambers.

A nematode disease of the dasheen and its control by hot-water treatment, L. P. Byars (Abs. in Phytopathology, 7 (1917), No. 1, p. 66).—The dasheen (Colocasia esculenta) is reported as having been found attacked by a nematode (Heterodera radicicola). The disease, it is claimed, can be successfully controlled by planting on uninfected land selected cormels from disease-free areas or diseased cormels which have been treated with water at 50° C. (122° F.) for 40 minutes.

A bacterial stem and leaf disease of lettuce, Nellie A. Brown (Abs. in Phytopathology, 7 (1917), No. 1, p. 63).—A wilt disease of lettuce is briefly reported, the disease having been observed in Beaufort County, S. C., in 1916. The affected plants were wilted and rotting was often rapid. Bacteria were abundant, and the organism isolated, when inoculated into lettuce, produced the blue-green color throughout the vascular system and pith which characterizes the normal appearance of the disease. The organism in its morphological and cultural characters is said not to correspond to any recorded as pathogenic to lettuce.

Studies upon the anthracnose of the onion, J. C. Walker (Abs. in Phytopathology, 7 (1917), No. 1, p. 59).—It is claimed that a morphological study of the organism Colletotrichum circinans confirms the findings of Voglino that the fungus belongs to the genus Colletotrichum and not Vermicularia. Inoculation of the fungus from onion into apple fruits is said to have resulted in a rot very similar to the Volutella rot, but further study is necessary before the two fungican be considered identical.

The fungus is said to winter over in the soil and consequently the disease is most severe on old onion fields. Spraying the bulbs before harvest or in the crates after harvest has not proved beneficial. Yellow and red varieties of onion are claimed to be highly resistant, and this fact is believed to offer encouragement for the development of a resistant white strain.

Pink root, a new root disease of onions in Texas, J. J. TAUBENHAUS and A. D. Johnson (Abs. in Phytopathology, 7 (1917), No. 1, p. 59).—A new disease of onions locally known as pink root is said to occur in Webb County, Tex., but only where onions are grown for two or more years on the same land. The roots of the affected sets in the seed bed or of the plants in the field turn pink in color, shrivel, and die. As fast as new roots are formed they become infected and the normal development of the bulbs is affected. The undersized bulbs resulting are worthless so far as market is concerned.

The cause of the disease has not yet been determined.

Black spot of pepper, L. E. Melchers and E. E. Dale (Abs. in Phytopathology, 7 (1917), No. 1, p. 63).—A disease of peppers is described with which a species of Alternaria has been constantly associated. Inoculation experiments have shown that the organism is only weakly pathogenic to normal tissue and that it becomes established largely through injuries to peppers in the field, the principal means being sun scald and frost injury.

Notes on curly dwarf symptoms on Irish potatoes, W. L. Durrell (Abs. in Phytopathology, 7 (1917), No. 1, p. 71).—Curly dwarf symptoms are said to have been very prevalent in Iowa during 1916, particularly on the varieties Irish Cobbler, Rural New Yorker, and Early Ohio. The disease made its appearance on the early plantings about June 10 and developed throughout the season. In August, plants that had been normal up to that time showed typical signs of curly dwarf on the foliage, and the upper third of the plants had shortened internodes and crinkled and curled leaves, giving the plants a bushy appearance. These symptoms are said to have been induced in the field by the hot, dry weather in August, and similar ones were later artificially developed in the

laboratory. The plants showing these symptoms put forth normal foliage again in September with the advent of cooler weather.

Histological studies showed that the crinkling of the leaves was due to necrosis of certain epidermal and cortical cells of the veins, followed by the growth of the parenchyma cells which induced buckling of the leaf surface. Transpiration experiments indicated that dwarfed plants transpire more rapidly than normal ones.

Notes on mosaic symptoms of Irish potatoes, I. E. Melhus (Abs. in Phytopathology, 7 (1917), No. 1, p. 71).—The author gives a description of the mosaic disease of potatoes and its effect on the production of tubers.

Frost necrosis of potato tubers, L. R. Jones and E. Balley (Abs. in Phytopathology, 7 (1917), No. 1, pp. 71, 72).—A type of noninheritable net necrosis of potato tubers is described, of which frost injury is apparently the primary cause. Experiments under artificial conditions have shown that exposure to freezing temperature may produce either ring or net necrosis. The stem end of the tuber is reported to be always more sensitive to injury than the other.

A bacterial blight of soy beans, A. G. Johnson and Florence M. Coerper (Abs. in Phytopathology, 7 (1917), No. 1, p. 65).—The authors report having had a bacterial blight of soy bean under investigation at Madison, Wis., for several years. The disease has become quite common, occurring especially on the leaves, on which the organism causes the production of small, angular spots which, in later stages, become dark in color. Repeated isolation cultures have yielded a characteristic organism which is referred to the genus Pseudomonas. Studies on the physiological characteristics of the organism and its pathogenicity are said to be in progress.

Further note on a parasitic saccharomycete of the tomato, A. Schneider (*Phytopathology*, 7 (1917), No. 1, pp. 52, 53).—In continuation of investigations of a disease of tomato previously reported (E. S. R., 36, p. 749), the author has concluded that the fungus is a new species, and it is technically described under the name Nematospora lycopersici.

Host limitations of Septoria lycopersici, J. B. S. Norton (Abs. in Phytopathology, 7 (1917), No. 1, p. 65).—Inoculation experiments in humid inclosures on seedlings of a number of species of Solanaceæ and 80 varieties of tomato with Septoria from tomato are said to have resulted in infections on several species of Solanum, eggplant, Datura tatula, potato, currant tomato, and S. carolinense. With larger plants outdoors, infection rarely occurs except on Lycopersicum.

Note on the genus Coniothecium, with special reference to C. chomatosporum, P. A. VAN DEB BIJL (So. African Jour. Sci., 12 (1916), No. 13, pp. 649-657, pls. 6, flgs. 2).—In view of a statement made by Massee (E. S. R., 34, p. 543), the author here presents more fully the results of an investigation, previously noted (E. S. R., 32, p. 344), which has not yet been completed.

This paper notes certain cultural characters of *C. chomatosporum*, the cause of a branch blister disease on apple and pear. The fungus develops between the cells, invading the middle lamellæ and rupturing the skin to produce the black blisters and fruit russeting. Evidence obtained is said to show that this organism is only a stage in the life cycle of *Phoma mali*.

Control of peach bacterial spot in southern orchards, J. W. ROBERTS (U.S. Dept. Agr. Bul. 548 (1917), pp. 7, pl. 1).—A description is given of the bacterial spot of peaches caused by Bacterium pruni. The disease, which is also known as bacteriosis, is said to occur in practically all the peach-growing sections of the eastern half of the United States, its most serious injury being confined to the most southerly portion of this district. Twigs, fruit, and leaves are affected, but the greatest amount of injury is done to the leaves.

Experiments carried on by the author and others indicate that the disease may be kept in check in southern peach orchards by proper pruning, cultivation, and especially fertilization. Of the fertilizers used, nitrate of soda proved most efficient.

In addition to the peach, B. pruni is said also to cause a disease of the plum, affecting especially the Japanese varieties.

Black currant eelworm, Miss A. M. Taylor (Jour. Agr. Sci. [England], 8 (1917), No. 2, pp. 246-275, pl. 1, flg. 1).—The author notes an attack of nematodes on black currant near Cambridge, England. The evidence indicates that this parasite has been established here for some time, probably having been more or less masked by its association with the black currant mite, the symptoms of the two as described being similar in some respects. Although a study which has been made of the nematode is given in some detail, its relationships have not yet been determined.

Sulphuring Concord grapes to prevent powdery mildew, F. E. GLADWIN and D. Reddick (Abs. in Phytopathology, 7 (1917), No. 1, p. 66).—The authors report the dusting of Concord grapevines with sulphur-lime mixtures containing 25, 50, and 75 per cent sulphur flour, 95 per cent or more of which would pass through a 200-mesh sieve. Comparisons were made with plants treated with Bordeaux mixture and where powdery mildew (Uncinula necator) was abundant, the vines receiving the dust mixture showed much less mildew on the grape clusters, although there was considerable burning with the larger amounts of sulphur-lime.

The generation of aldehydes by Fusarium cubense, E. C. LATHROP (Phytopathology, 7 (1917), No. 1, pp. 14-16).—Investigations having shown that aldehydes of various chemical constitution are detrimental to plant growth, the author experimented with F. cubense, the cause of the Panama banana disease, and found that aldehydes were formed during the growth of the fungus on synthetic culture media. The generation of aldehydes by F. cubense is believed to account, in a measure at least, for the pathological action of the organism.

Citrus canker investigations at the Florida Tropical Laboratory, R. A. Jehle (Abs. in Phytopathology, 7 (1917), No. 1, pp. 58, 59).—A description is given of some cultural characteristics of the canker organism, Pseudomonas citri, as obtained in the laboratory. Positive results are reported to have been secured from inoculations on grapefruit, ponderosa lemon, key lime, Citrus trifoliata, sour orange, tangelo, sweet orange, tangerine, king orange, mandarin lime, and kumquat. The disease also occurs on navel orange, mandarin, satsuma, common lemon, rough lemon, and Ægle glutinosa.

Sour rot of lemon in California, C. O. SMITH (Phytopathology, 7 (1917), No. 1, pp. 37-41, figs. 2).—A description is given of a sour rot of lemons and other citrus fruits occurring during storage. The infected tissues soften, become straw-colored, and collapse, changing into a more or less slimy, watery mass.

A fungus has been isolated from diseased fruits which is considered identical with Oospora citri-aurantii, originally described by Ferraris (E. S. R., 14, p. 161). Artificial inoculations of the fungus on citrus fruits in moist chambers gave positive results with lemons, oranges, grapefruit, and tangerines, the rot showing within 48 hours. Green fruit of lemons, as well as twigs of Eureka lemon, when inoculated, gave negative results.

From the author's experiments, it is concluded that infection of lemons with the sour rot fungus takes place only through some injury or from contact with infected fruit.

Two new camphor diseases in Texas, J. J. TAUBENHAUS (Abs. in Phytopathology, 7 (1917), No. 1, pp. 59, 60).—Anthracnose of camphor, due to a species

of Gleosporium which is tentatively named G. camphoræ n. sp., and a limb canker of camphor are briefly described.

Diseases of cinchona, A. RANT (Meded. Kina Proefstat. [Dutch East Indies], No. 2 (1914), pp. 47, pls. 11).—The author has listed with brief discussion the known diseases of adult plants of cinchona, grouped according to the portions affected, namely, leaves, branches, stems, and roots, and also separately the diseases affecting more particularly the young plants.

A disease of pecan catkins, B. B. Higgins (Phytopathology, 7 (1917), No. 1, pp. 42-45, figs. 2).—The author's attention was called during the spring of 1916 to an abnormality of the staminate catkins of pecans on the Georgia Experiment Station plats. An examination of the catkins showed the presence of a fungus in the infected anthers, which, while not killing the tissues outright, caused many of the pollen grains to become empty and to collapse.

A study of the trouble showed it to be due to a species of Microstroma, and as a similar fungus was observed on the leaves of hickory trees, it was suspected that the one on pecan was identical with that on hickory. Cultures of both forms were obtained and some differences were noted. Diligent search indicated that the fungus on pecan catkins differs from that on hickory, and the organism is technically described under the name *M. juglandis robustum* n. var. As pollen is always produced in great abundance by pecan trees, the loss of a comparatively large amount is considered of little importance, but the author suggests that this disease may become serious in the future.

Phytophthora on Vinca rosea, J. F. Dastur (Mem. Dept. Agr. India, Bot. Ser., 8 (1916), No. 6, pp. 233-242, figs. 14).—During the wet period occurring in May and June, 1913, V. rosea suffered much from a parasitic fungus which was diagnosed as a Phytophthora. The attack weakens or disappears in dry weather and sunshine. The organism, which appears to be a weak parasite, has been studied by the author and is considered to be a biological strain of P. parasitica, previously described by him as a new species attacking the castor oil plant (E. S. R., 29, p. 548).

Notes on some species of Coleosporium, G. G. Hedgecock and N. R. Hunt (Abs. in Phytopathology, 7 (1917), No. 1, p. 68).—C. delicatulum is reported for the first time on two species of Euthamia, and the Peridermium form on a number of species of Pinus. The occurrence of C. laciniaria on six species of Laciniaria is also reported.

The æcial stage of Coleosporium elephantopodis, G. G. Hedgeck and W. H. Long (Abs. in Phytopathology, 7 (1917), No. 1, pp. 66, 67).—Young trees of Pinus heterophylla in the greenhouse at Washington, D. C., inoculated with teliospores of C. elephantopodis, are said to have produced æcia of Peridermium carneum. Inoculations with æciospores on the leaves of Elephantopus tomentosus produced both uredinia and telia of C. elephantopodis. Parallel sets of inoculations of plants of Vernonia and Elephantopus gave results indicating the identity of the two species of Coleosporium previously reported on the two hosts. Peridermium carneum is reported for the first time on the needles of Pinus caribwa, P. clausa, P. echinata, P. glabra, P. heterophylla, P. ponderosa, P. rigida, P. scopulorum, and P. serotina.

An alternate form for Coleosporium helianthi, G. G. Hedgock and N. R. Hunt (Abs. in Phytopathology, 7 (1917), No. 1, pp. 67, 68).—Peridermium helianthi is described on Pinus virginiana. Inoculations made with the eclospores of the Peridermium on Helianthus decapetalus, H. divaricatus, H. giganteus, H. glancus, and H. hirsutus proved the Peridermium to be the eclal stage of C. helianthi.

Some new hosts for Coleosporium inconspicuum, G. G. Hedgeock and N. R. Hunt (Abs. in Phytopathology, 7 (1917), No. 1, pp. 68, 69).—The Peridermium

form of this fungus is reported for the first time on *Pinus echinata*. This material was used in inoculating *Coreopsis major æmleri* and *C. verticillata*, resulting in the formation of uredinia and telia of *Coleosporium inconspicuum*.

The Peridermium belonging to Coleosporium ipomææ, G. G. Hedgecock and N. R. Hunt (Abs. in Phytopathology, 7 (1917), No. 1, p. 67).—The authors describe P. ipomææ, a new folicolus species on Pinus echinata, P. palustris, P. rigida, and P. tæda. Plants of Ipomæa lacunosa, I. pandurata, I. triloba, Pharbitis barbigera, P. hederacea, and Quamoclit coccinea under controlled conditions were successfully inoculated with the æciospores of this Peridermium, producing on their foliage the typical uredinia and telia of C. ipomææ.

Some new hosts for Coleospérium solidaginis, G. G. Hedgoock and N. R. Hunt (Abs. in Phytopathology, 7 (1917), No. 1, p. 68).—Peridermium acicolum, the æcial stage of C. solidaginis, is reported for the first time on species of Pinus, and positive results are said to have been obtained from inoculations with the æciospores of P. acicolum on plants of species of Aster and Solidago.

A Peridermium belonging to Coleosporium terebinthinaceæ, G. G. Hedgecock and N. R. Hunt (Abs. in Phytopathology, 7 (1917), No. 1, p. 67).—The authors describe a new folicolus species, P. terebinthinaceum, occurring on Pinus echinata, P. rigida, and P. tæda, with a range from North Carolina to Georgia. Inoculations were made under controlled conditions with the æciospores of this Peridermium on plants of Silphium asteriscus, S. integrifolium, S. trifoliatum, and Parthenium integrifolium, and in about two weeks the uredinia and later the telia of C. terebinthinaceæ appeared on the leaves of all these species. C. terebinthinaceæ has been reported on the leaves of S. angustum, S. compositum, S. dentatum, S. glabrum, and S. pinnatifidum.

Notes on Cronartium comptoniæ, III, P. Spaulding (*Phytopathology*, 7 (1917), No. 1, pp. 49-51).—In continuation of notes on this and related fungi (E. S. R., 33, p. 351), the author presents additional data.

The additional pine hosts, Pinus densifiora, P. jeffreyi, P. laricio, P. mugho, and P. resinosa, have been reported for C. comptonia. Uredinia have been produced on plants of Comptonia asplenifolia with aciospores from a number of species of Pinus. Uredinia on Comptonia were successfully used to produce uredinia on Comptonia and Myrica gale. Uredinia from M. gale produced uredinia on Comptonia.

Observations made by the author in a number of localities have shown that *Cronartium comptoniæ* fruits on pines principally in a period of seven or eight weeks, reaching its maximum about June 1, a date considerably earlier than that previously reported. The author believes that *P. rigida* is much less susceptible to the disease than are *P. pondcrosa* and *P. contorta*, the loss among which has been total.

Does Cronartium ribicola winter on the currant? W. A. McCubbin (*Phytopathology*, 7 (1917), No. 1, pp. 17-31, ftg. 1).—In continuation of a previous note (E. S. R., 36, p. 652), the author offers data to substantiate his hypothesis that *C. ribicola* hibernates as mycelium in infected buds of currant. This is believed to be in agreement with known habits of other rusts under like conditions and of similar nature and is supported by the general and irregular appearance of the currant stage of the fungus over large areas in which there is reason to believe that there are no pine infections. Special cases where rust has occurred on currants which are distant from any possible source of infection are reported, and in one instance the only case of rust in one large black currant plantation was on two of four plants which had been badly infected in the preceding year. A report is also given of the occurrence of currant rust on plants set out in a rust-free district in order to test overwintering.

Evidence of the overwintering of Cronartium ribicola, P. SPAULDING (Abs. in Phytopathology, 7 (1917), No. 1, p. 58).—The author reports that currants are frequently infected with C. ribicola one summer but not the next and, further, that cooperative experiments in which 500 heavily infected black currants were used resulted in no disease. The author states that he has had under observation for seven years in greenhouses in Washington, D. C., hundreds of Ribes plants used in inoculation experiments, and in no case has the disease ever appeared the next season until artificial inoculations have been made. It is claimed that infection of petioles is not so rare as has been supposed, that no evidence of bud infection by way of the petiole has been obtained, and that direct examination of buds of infected plants has failed to show the presence of the fungus.

The pine blister, B. H. Paul (N. Y. State Conserv. Com. Bul. 15 (1916), pp. 18, pl. 1, figs. 8).—This is a résumé of the proceedings of a conference held by the committee for the suppression of pine blister in North America at Albany, N. Y., November 20 and 21, 1916. A general account is given of the characteristics and importance of the disease in the United States and Canada, also the result of preliminary work showing the distribution of the disease as known to date, with recommendations and other information looking toward its control.

The control of white pine blister rust in small areas, W. H. RANKIN (Abs. in Phytopathology, 7 (1917), No. 1, p. 58).—A brief account is given of experiments in control of white pine blister rust on 85 forest plantings in New York State. Diseased or suspicious trees and all species of Ribes were removed within 500 ft. of the plantings, and the results obtained seem to indicate that this treatment prevented the appearance of Cronartium ribicola in these areas.

Some new or little known hosts for wood-destroying fungi, A. S. Rhoads (*Phytopathology*, 7 (1917), No. 1, pp. 46-48).—A list is given of host species of 16 wood-destroying fungi, the species being believed to be new or at least little known hosts for these fungi, which have not been previously reported upon them.

## ECONOMIC ZOOLOGY-ENTOMOLOGY.

A new subspecies of meadow mouse from Wyoming, V. Balley (Proc. Biol. Soc. Wash., 30 (1917), pp. 29, 30).

Diagnosis of a new laniine family of Passeriformes, H. C. OBERHOLSER (Jour. Wash. Acad. Sci., 7 (1917), No. 7, pp. 180, 181).—The family Tylidæ is erected.

Description of a new Sialia from Mexico, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 30 (1917), pp. 27, 28).

Friends of our forests, H. W. Henshaw (Nat. Geogr. Mag., 31 (1917), No. 4, pp. 297-321, figs. 33).—Brief accounts illustrated by colored plates, prepared by L. A. Fuertes, are given of 36 species of North American warblers.

Report of the entomologist of the Arizona Commission of Agriculture and Horticulture for the year ended June 30, 1916, A. W. Morrill (Ariz. Com. Agr. and Hort. Ann. Rpt., 8 (1916), pp. 11-57, pls. 3, figs. 17).—The first part of this report (pp. 11-30) deals with inspection work, the alfalfa weevil protective service, insect control and eradication, etc. Part 2 (pp. 31-49) consists of notes on the more important insects of the year, and part 3 (pp. 51-57) takes up three plant diseases in 1916, namely, citrus gummosis, citrus scaly bark, and pear blight.

The more important insects of the year are considered under the headings of pests of deciduous fruits, small fruits, and vines; citrus and olive pests; pests of field and forage crops; vegetable crop pests; and cotton pests. During the year four species of insects and one species of red spider, not previously

recorded as of economic importance, became injurious to crops in Arizona. These consist of a nitidulid beetle (Conotelus mexicanus) destructive to fruit blossoms, a variety of false chinch bug (Nysius minutus) destructive to flaxseed, a cotton stainer (Dysdercus albidiventris) injurious to cotton bolls, and a red spider (Tetranychus modestus) injurious to corn. Aside from these, the most noteworthy insect records of the year consist of that of a cornstalk borer, thought to be the larger cornstalk borer (Diatræa zeacolella), and that of an apparently new moth borer of pear trees.

Annual report of the State entomologist for 1915, E. L. Worsham (Ga. Bd. Ent. Bul. 45 (1916), pp. 31, pl. 1, figs. 3).—This reports upon the occurrence of the more important insects of the year in Georgia, particularly the boll weevil, and includes an account by I. W. Williams of cotton breeding work, of truck crop pests and miscellaneous insects affecting shade trees and ornamental plants, a report by C. S. Spooner on pecan pests, etc. A map showing the area in Georgia infested by the boll weevil in 1915 and the quarantined area in 1916 is attached.

Report of the division of entomology for the biennial period ending December 31, 1916, E. M. Ehrhorn ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1915–16, pp. 79–109, pl. 1).—This, the usual biennial report on inspection and other work of the year (E. S. R., 34, p. 59), includes a classified list of the insects collected. A report by D. T. Fullaway on beneficial insects (pp. 105–109) deals briefly with the parasites of the melon fly, corn leaf-hopper, fruit fly, mealy bug, and horn fly, and gives a tabulated list showing the liberation of beneficial insects in 1915–16.

Report of the economic biologist, G. E. Bodkin (Rpt. Dept. Sci. and Agr. Brit. Guiana, 1915, App. 3, pp. 10).—The author reports upon the occurrence of and work with the more important insect pests of the year in British Guiana.

Observations on some insects attacking rice, F. Supino (R. Ist. Lombardo Sci. e Let. Rend., 2. ser., 49 (1916), No. 2-3, pp. 108-114).—Three aquatic insects that are of importance in rice fields near Milan are reported upon by the author, namely, Stratiomys chamæleon, Triænodes bicolor, and Hydrocampa (Nymphula) nymphæata.

Wild vegetation as a source of curly-top infection of sugar beets, P. A. Boncquet and C. F. Stahl (Jour. Econ. Ent., 10 (1917), No. 4, pp. 392-397, pls. 2).—Malva rotundifolia, a common weed in sugar beet fields, has proved to be at least a symbiotic host of the virulent factor of curly-top of sugar beets. Beet leaf hoppers, which were known to be nonvirulent when placed on sickly-looking mallow plants in the field and subsequently on healthy beets, produced curly-top in four experiments. "Insects known to be virulent were placed on healthy seedlings of M. rotundifolia. After a certain lapse of time they were removed and replaced with nonvirulent insects which were later transferred to healthy beets. All transfers brought about the disorder."

Meadow and pasture insects.—Practical methods of control for the more common forms, H. Osborn (Mo. Bul. Ohio Sta., 2 (1917), No. 8, pp. 268-273).—A brief discussion of meadow and pasture insects and means for their control. The difficulties to be met with in their control are pointed out and emphasis placed upon the importance of crop rotation. The control measures applicable for permanent pastures and meadows consist of burning, hopperdozers or hopper catchers, baiting, and trap lights. Brief reference is made to their natural enemies.

Insects that factor in the grading of apples, P. J. PARROTT (West. N. Y. Hort. Soc. Proc., 62 (1917), pp. 72-81, figs. 2; Rochester, N. Y.: Davis and Jeens Printing Co., 1917, pp. 10, figs. 2).—An address, delivered before the Western

New York Horticultural Society on January 24, 1917, in which it is shown that the codling moth was by far the most important of the insects responsible for apple deformation during 1916, having been responsible for  $58\frac{1}{2}$  per cent. It is followed in importance by aphids,  $12\frac{2}{3}$  per cent; red bugs,  $9\frac{2}{3}$ ; curculio,  $4\frac{1}{3}$ ; lesser apple worm,  $4\frac{1}{3}$ ; leaf roller,  $3\frac{2}{3}$ ; green fruit worm,  $1\frac{1}{3}$ ; San José scale, 1; case bearers,  $\frac{2}{3}$ ; bud moth,  $\frac{1}{3}$ ; Palmer worm,  $\frac{1}{3}$ ; apple maggot,  $\frac{1}{3}$ ; and other insects, 1.

Spraying for insects affecting apple orchards in Nova Scotia, G. E. Sanders and W. H. Brittain (Canada Dept. Agr., Ent. Branch Circ. 8 (1916), pp. 11, pl. 1).—This circular contains the results of spraying experiments carried on in Nova Scotia during the last two years, together with notes on the control of certain insects affecting apples and pears that are prevalent at the present time. A spray calendar, revised to include the results of later work, is also included.

Insects injuring stored food products in Connecticut, W. E. Britton (Connecticut State Sta. Bul. 195 (1917), pp. 3-21, figs. 18).—A brief summary of information on stored food products insect pests, to which is added information on control measures.

The carriage of disease by insects, L. O. Howard (Jour. Wash. Acad. Sci., 7 (1917), No. 8, pp. 217-222).—This is an abridgment of the presidential address delivered before the Washington Academy of Sciences on February 1, 1917.

A key for the identification of animal parasites found in the human feces, H. G. MARTIN and L. S. McKittrick (Bul. Univ. Wis., No. 828 (1917), pp. 24, figs. 43).—An illustrated key.

Volatility of organic compounds as an index of the toxicity of their vapors to insects, W. Moore (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 7, pp. 365-371, figs. 7).—This is a report of investigations carried on at the Minnesota Experiment Station in continuation of those previously noted (E. S. R., 37, p. 559). By applying the chemicals to a strip of filter paper suspended in a flask the actual amount necessary to kill the housefly in 400 minutes was determined for a large number of chemicals, the results of which are here recorded.

"In general the toxicity of a volatile organic compound is correlated closely with its volatility. A decreasing volatility is accompanied by an increased toxicity. The boiling point of the chemical is a general index of its volatility. Compounds with boiling points of 225 to 250° C, are usually so slightly volatile that they do not produce death except after very long exposures. The structure of the respiratory system of the insect is probably responsible for the remarkable influence of volatility on the toxicity of the vapor of volatile organic compounds."

Lead arsenates, stone fruits, and the weather, G. P. Gray (Jour. Econ. Ent., 10 (1917), No. 4, pp. 385–392, pl. 1).—Investigations of injury to stone fruits in California during April, 1915, have shown that the acid type of lead arsenate, often labeled "standard," is unsafe to use on the foliage of these fruits except under favorable weather conditions. Pome fruits sprayed under the same conditions for the control of cankerworm showed no injury. The foliage injury in the orchards of the Santa Clara Valley in the spring of 1915 was due to the decomposition of acid lead arsenate by the weather. The basic type of lead arsenate usually labeled "triplumbic" or "neutral," which is a slower acting poison, is a safer arsenical to use on stone fruits.

Locust control in various countries, G. TRINCHIERI (La Lutte Contre les Sauterelles dans les Divers Pays. Rome: Inst. Internat. Agr., 1916, pp. XVI+187; rev. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 3, pp. 100, 101).—In an introduction by Saulnier (pp. IV-XVI) the circumstances relating to the compila-

tion of this report by the author from information collected by means of a questionnaire circularized throughout the world are described.

The report considers the history and geographical distribution of locusts; gives a list of 142 injurious species observed in different countries and the locality in which each occurs, together with their food plants; and discusses the biology and habits of locusts and control organization in each country. The methods of control are discussed under the headings of natural enemies and mechanical, physical, and chemical methods. The work concludes with a discussion of an international understanding on the question of control, the following countries being reported as approving the principles of such an agreement: Portugal, Spain, Italy, Austria-Hungary, Roumania, Greece, China, India, Morocco, Tunis, Kamerun, Canada, the United States, Mexico, and Trinidad.

A 24-page bibliography is included.

Report on control work with the locust in Uruguay, R. Sundberg et al. (Defensa Agr. [Uruguay] Mem., 1916, pp. 444, pls. 51).—This report presents the details relating to work in Uruguay during 1915—16 and includes numerous large-sized colored maps showing the dissemination of and control work with the locust.

Experiments in locust control by means of Coccobacillus acridiorum in Argentina, R. Kraus (Centbl. Bakt. [etc.], 2. Abt., 45 (1916), No. 18-25, pp. 594-599; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 9, pp. 1383, 1384).—This paper is based upon investigations conducted by the author, as a member of a commission appointed by the Minister of Agriculture of Argentina, with a view to repeating the experiments of d'Herelle.

Organisms, morphologically identical with *C. acridiorum*, were isolated from the intestines of healthy locusts. The author was able to increase the virulence of the coccobacillus of d'Herelle and also found that the same effect can be obtained equally well with the micro-organisms from the intestines of locusts, although only negative results followed the feeding of locusts upon such organisms. His conclusions are as follows:

"It is not possible to produce in the open field the epidemic infection and the death of young locusts by spraying with a culture of coccobacillus, the virulence of which has been increased by successive passages. It may thus be concluded that this coccobacillus is a normal inhabitant of the intestine of healthy locusts and that it only kills the latter when injected into the abdominal cavity. By administering this bacterium to young locusts with food, no infection is obtained."

Summary of locust work for the third quarter, 1916, F. W. South (Agr. Bul. Fed. Malay States, 5 (1916), No. 3, pp. 64-72).—This is a report of work carried on in the Federated Malay States.

A new Sericothrips from Africa, J. D. Hoop (Bul. Brooklyn Ent. Soc., 12 (1917). No. 2, pp. 32-34).

A new species of Corythuca from the Northwest, E. H. Gibson (*Ent. News*, 28 (1917), No. 6, p. 258).—Corythuca pura, collected from the prairie sunflower (*Balsamorhiza sagittata*) in several localities in the northwestern United States, is described as new.

The tomato and laurel psyllids, E. O. Essig (Jour. Econ. Ent., 10 (1917), No. 4, pp. 433-444, pl. 1, figs. 2).—Studies of 2 of the 50 species described from California, namely, the tomato psyllid (Paratrioza cockerelli) and the laurel psyllid (Trioza alacris), have been made by the author and are here reported upon.

The pink and green potato plant louse.—A new pest for Ohio causing serious losses this year, J. S. Houser (Mo. Bul. Ohio Sta., 2 (1917), No. 8, pp.

261-267, figs. 6).—A summary of information on Macrosiphum solanifolii, the first destructive outbreak of which in Ohio took place during 1917 and similar outbreaks occurred in Illinois and Missouri. In the vicinity of Cincinnati the attack, which started about the first of June, was so severe that within a few weeks entire fields were brown and dead. It was first observed to attack early potatoes and later spread to include early tomatoes and a rather wide range of host plants. Where potatoes were badly infested the vines were completely killed, while lighter infestations resulted in curling and distortion of the tops which stunted the plants and materially decreased the yield of tubers. On tomatoes the leaves were affected, but the main injury was to the blossom stems where the plant lice collected in enormous numbers, causing the blossoms to fall so that no tomatoes set. In one tomato field an expected return of about \$900 an acre was reduced to not more than \$100 an acre.

In control work in the Cincinnati district the most satisfactory material was nicotin sulphate used at the rate of 1 to 2 teaspoonfuls to 1 gal. of water, or a half pint to 50 gal. of water, with enough soap added to form suds. When desired nicotin sulphate may be used in combination with lead arsenate or Bordeaux mixture, or in a mixture of both, but when combined with either or both soap should not be used. Several applications should be made, preferably every other day for perhaps four or five times, depending upon the weather, in order to insure the destruction of the plant lice. The importance of directing the spray upward to reach the plant lice on the underside of the leaves is emphasized.

Some sensory structures in the Aphididæ, A. C. BAKER (Canad. Ent., 49 (1917), No. 11, pp. 378-384, figs. 48).

Eastern aphids, new or little known, I, EDITH M. PATCH (Jour. Econ. Ent., 10 (1917), No. 4, pp. 416-420, fig. 1).—This paper, based largely on a collection of Connecticut plant lice, includes descriptions of Aphis viburniphila n. sp. from several species of Viburnum, A. rumexicolens n. sp., from Rumex acetosella, and Prociphilus approximatus n. sp., from white ash.

Eastern aphids, new or little known, II, A. C. Baker (Jour. Econ. Ent., 10 (1917), No. 4, pp. 420-433, fig. 1).—This second paper includes keys to the American species of several genera, namely, Myzocallis, Monellia, Euceraphis, Chaitophorus, and Pterocomma. Five species are described as new to science.

The Aphididæ of Java, P. van der Goot (Inst. Sci. Buitenzorg, Contrib. Faune Indes Néerland., 1 (1917), No. 3, pp. 1-301, figs. 52).—This summary of the knowledge of plant lice in Java includes descriptions of 2 new tribes, 14 new genera, and 54 species new to science. An index to the species of plant lice thus far known to occur in Java, namely, 82 species representing 34 genera, and a host plant index of the same are included, as is a list of 21 references to literature.

[Studies of pediculi] (Parasitology, 9 (1917), No. 2, pp. 228-265, 293-324, pls. 2, flgs. 16).—Several papers relating to pediculi, here presented, include A Contribution to the Bionomics of Pediculus humanus (vestimenti) and P. capitis, by A. Bacot (pp. 228-258), consisting of a detailed report of life history studies, given to a large extent in tabular form; Notes on the Biology of P. humanus, by E. Hindle (pp. 259-265); and Studies on Pediculus.—I, The Copulatory Apparatus and the Process of Copulation in P. humanus, by G. H. F. Nuttall (pp. 298-324).

The louse problem, A. W. Bacot (Brit. Med. Jour., No. 2931 (1917), pp. 296, 297).—The data here presented are based upon the studies above noted.

The isolation of the Bacillus typhi-exanthematici from the body louse, P. K. OLITSKY, B. S. DENZER, and C. E. HUSH (Jour. Amer. Med. Assoc., 68 (1917), No. 16, pp. 1165-1168).—"Since 1910 many observers in different parts

of the world have reported the finding of an organism in typhus-infected lice. This organism they believe to have a causal relationship to typhus fever. Owing to the fact that improper methods have been used, culture of this organism was impossible. In Mexico we have been able to grow this bacterium and to show that morphologically, culturally, and serologically it is identical with B. typhi-exanthematici."

The lesser corn stalk borer, P. LUGINBILL and G. G. AINSLIE (U. S. Dept. Agr. Bul. 539 (1917), pp. 27, pls. 3, flgs. 6).—This is a report of studies conducted by the senior author at Columbia, S. C., during the seasons 1913, 1914, and 1915, and by the junior author at Lakeland, Fla., during 1913 and 1914.

The phycitid moth *Elasmopalpus lignosellus*, which has heretofore occurred in injurious abundance only in sporadic outbreaks, has now become of considerable economic importance in the Southern States. While particularly important as an enemy of corn, cowpeas, sorghum, and beans, it also attacks chufa (*Cyperus esculentus*), crab grass (*Eleusine indica*), Japanese cane, Johnson grass, milo maize, peanuts, sugar cane, turnips, and wheat. Though the larvæ are omnivorous, the investigations show that they have a decided fondness for Gramineæ, and probably would confine themselves almost exclusively to plants of this family if they were always obtainable. Crops grown on sandy soils or soils lacking humus are usually the most seriously affected.

The injury is caused by the larvæ boring into the stems of growing plants and feeding therein, such injury being particularly characteristic in young corn and sorghum, where the larvæ tunnel into the stalks at or slightly below the surface of the ground, through and sometimes up the heart for a distance varying from 1 to 2 in. The bud leaves of the affected plants are severed from the main plant, injury to corn in this manner resembling closely the work of the southern corn root worm (Diabrotica 12-punctata), but E. lignosellus is an upland species, found only in the driest of soils, while the corn root worm breeds generally in the moist lowlands. While some of the injured plants may survive, they remain dwarfed or become deformed. In older corn, sorghum, and cowpeas the damage consists primarily in the girdling of the stems at or slightly below the surface of the ground, and the larvæ also tunnel into the stems, thereby weakening them to such an extent that very little pressure is required to break them off. Cowpea plants have been found almost completely cut in two at a point near or slightly below the surface of the ground by the larvæ girdling the stem, while in other cases the larvæ were found tunneling into the stems as in the case of corn and sorghum. The larvæ in all stages spin a silken thread wherever they go, and the younger ones readily suspend themselves by it.

Originally described by Zeller in 1848 from Brazil, Uruguay, Colombia, and "Carolina," U. S. A., this moth is now known to occur in the United States throughout all the Southern States, westward, including the southern parts of New Mexico, Arizona, and California, and northward, including Oklahoma, eastern Kansas, southeastern Nebraska, southern Iowa, Illinois, Indiana, and Ohio, southeastern Pennsylvania, New Jersey, and along the Atlantic coast into Massachusetts.

Technical descriptions are given of its several stages, which include six larval instars. Oviposition apparently does not take place when the temperature falls much below 80° F. The eggs, which are thought to be deposited on the stems of plants, in the axils of the leaves, or on the ground at or near the bases of the stalks, hatch in 3 days in summer, 5 days in early fall, and in from 6 to 8 days in late fall. The number deposited under laboratory conditions varied from 91 to 342, with an average of 190, as many as 73 eggs being deposited in a single day. The larvæ may reach maturity in 13.8 days, but generally in about 16.8+ days during the summer months and from 22+ to

41.6 days in the fall. The number of instars and their length is quite variable, the larvæ molting four or five times in summer and five or six times in the fall. The length of the pupal stage varies from 7 to 11 days in July, 7 to 10 days in August, 8 to 18 days in September and October, and from 9 to 21 days in October and November. The longevity of the adults in rearing cages averaged 12.7 days for the summer months.

There are thought to be four generations of this species at Columbia, S. C., three complete generations having been reared from the middle of June to the middle of October in 1913. In the latitude of Columbia the first part of the winter is apparently passed as a larva and the latter part as a pupa and possibly adult, the larvæ having been found in the field in their burrows in the stalks as late as the middle of November. In Arizona it is thought to pass the winter in the larval stage, since larvæ in all sizes were found at Tempe as late as November 3.

The species apparently suffers very little from natural enemies, a single parasite (*Neopristomerus* sp.) having been reared at Columbia, S. C., and *Orgilus læviventris* at Gainesville, Fla.

Much can be accomplished in the control of this pest through late fall and early winter plowing after the removal or destruction of all remnants and waste material in the field, harrowing of the borders and terraces to break up the winter quarters of pupæ, the use of fertilizer to stimulate plant growth and make the plants more resistant to attacks by the pest, and the early planting of corn, sorghum, and allied crops to give the plants in the infested soil a good start before the insect begins its depredations.

An annotated bibliography of 27 titles is included.

Control of the grape-berry moth in the Erie-Chautauqua grape belt, D. ISELY (U. S. Dept. Agr. Bul. 550 (1917), pp. 42, pls. 6, flgs. 9).—This bulletin, which relates particularly to control measures, is prefaced by a brief account of the economic status and a summary of seasonal history and habits of Polychrosis viteana, based upon observations by the author and his associates at North East, Pa., during the seasons of 1914, 1915, and 1916, and the work of Johnson and Hammar, previously noted (E. S. R., 28, p. 453).

The work has shown that the pest can be controlled by spraying, and that while other methods will reduce berry-moth infestation and some of them can be employed profitably to increase the efficiency of spraying, none offers a dependable control in commercial vineyards. The spray mixture recommended consists of arsenate of lead paste 3 lbs. or powder 1.5 lbs. and resin fish-oll soap 1 lb. in Bordeaux mixture (3:3:50). In case of extremely heavy infestation the amount of arsenate of lead should be increased to 5 lbs. paste or 2.5 lbs. powder, at least in the last application. The spray should be applied with "trailers," the first application immediately after falling of the grape blossoms and the second application (about two weeks later) when the grape berries are just touching. The cost of spraying material and labor required to control the grape-berry moth, if applied to control the berry moth alone, is about \$5 per acre, it being assumed that an average of 6 acres are sprayed per day and that 150 gal. of liquid are applied to the acre.

"The applications of spray materials required for the control of the grapeberry moth are so timed that they may be combined with applications to control the grape rootworm, grape leafhopper, and powdery mildew, and some of the applications for downy mildew and black rot also may be combined with them. Nothing need be added to the spray solution for rootworm control; nicotin sulphate (40 per cent) at the rate of 1:1,600 should be added to the second application for leafhopper control; and Bordeaux mixture should be used in both applications for fungus diseases." The other control measures considered include destruction of leaves in the fall, bagging grape clusters, hand picking infested berries, early harvesting, burying hibernating pupæ, etc.

A report of studies of this pest in Ohio by Goodwin has been previously noted (E. S. R., 35, p. 358).

On the pathogenicity of the so-called Sotto bacillus of silkworms, K. Aoki and Y. Chigasaki (Bul. Imp. Sericult. Expt. Sta. Japan, 1 (1916), No. 1, pp. 97-139).—The investigations show that the fatal action of old agar cultures of Bacillus sotto is due to a toxin which occurs in the spores.

The atoxogen type of Bacillus sotto, A. Aoki and Y. Chigasaki (Bul. Imp. Sericult. Expt. Sta. Japan, 1 (1916), No. 1, pp. 141-149).—A strain of B. sotto discovered by the authors—the atoxogen type—did not produce a fatal toxin when grown in agar culture, but did, however, possess the power to produce a septicemia. It was found that the so-called atoxogen and toxogen strains can be distinguished neither culturally or through immunization.

Flight of mosquitoes.—Studies on the distance of flight of Anopheles quadrimaculatus, J. A. A. LEPRINCE and T. H. D. GRIFFITTS (Pub. Health Rpts. [U. S.], 32 (1917), No. 18, pp. 656-659, figs. 3).—"Observations on the flight of A. quadrimaculatus in nature showed the flight to extend to approximately a mile from a breeding place producing very profusely. Beyond this distance stained specimens were not found. The distance of flight from a place producing very freely but less profusely than the above was decidedly less, approximately a half mile. Stained specimens of A. quadrimaculatus were taken as follows: One at 5,565 ft. from the point of liberation, two at 3,245 ft., three at 3,090 ft., one at 2,800 ft. A. quadrimaculatus, in one test, flew across a river 800 ft. wide in returning to a plantation from which they were originally caught for the test. Approximately 900 or 1,000 mosquitoes were liberated."

Notes on the early stages of Chrysops, W. Marchand (Jour. N. Y. Ent. Soc., 25 (1917), No. 3, pp. 149-163, pls. 3).—A contribution from the department of animal pathology of the Rockefeller Institute for Medical Research, Princeton, N. J., consisting of notes on the egg-laying habits and the earlier stages of Tabanidæ or horseflies of the genus Chrysops. Twelve of the 34 species occurring in New Jersey were found at Princeton.

Sarcophaga hæmorrhoidalis larvæ as parasites of the human intestine, L. HASEMAN (Ent. News, 28 (1917), No 8, pp. 343-346).—This reports cases of parasitism by S. hæmorrhoidalis in Missouri.

Fly investigation reports, I-III, WINIFRED H. SAUNDERS (Proc. Zool. Soc. London, No. 3 (1916), pp. 461-463, 465-468, 469-479; abs. in Rev. Appl. Ent., Ser. B, 4 (1916), No. 11, pp. 167, 168).—The first part of this report relates to some observations on the life history of the blowfly and of the house fly, made from August to September, 1915; the second part to trials for catching, repelling, and exterminating flies in houses, made during the year 1915; and the third part to investigations with stable manure to check the breeding of house flies, made during the year 1915.

As reported in the third paper, the author has found two very successful methods of treating stable manure for the destruction of flies, the first consisting in a surface dressing of the manure with green tar oil or with neutral blast furnace oil and soil at the rate of 1 part of oil to 40 parts of soil, and the second, the application of tetrachlorethane in the miscible form at the rate of 2 oz. to 10 cu. ft. of manure. Both treatments killed the maggots successfully and are harmless to plants. Tar oil has a permanent effect in being resistant to rain while the effect of the tetrachlorethane lasts only while the liquid vaporizes.

Flies and typhoid, W. Nicoll (Jour. Hyg. [Cambridge], 15 (1917), No. 4, pp. 505-526).—"The chain of evidence incriminating the house fly as a disseminator of typhoid fever is at present fairly complete, but many of the links are weak and not thoroughly strengthened by experimentation. The bulk of experimental work has hitherto been done under highly unnatural and artificial circumstances and the results so obtained can not be accepted unreservedly as giving a correct view of conditions in nature.

"The experiments described in the present paper show that flies can ingest typhoid bacilli from natural matter, i. e., human feces and urine, and carry them for a certain period of time. There is no evidence to show that the typhoid bacilli multiply in the house fly. On the contrary the evidence goes to show that they are not adapted for prolonged life on or in the fly. It thus follows that the house fly is a purely mechanical carrier of the typhoid bacillus and is not a natural 'host' in the strict sense of the term.

"Many bacilli closely resembling Bacillus typhosus in cultural characteristics appear to be natural or, at least, common inhabitants of the intestine of the house fly. These are extremely likely to be mistaken for B. typhosus unless the most stringent tests are employed. As might be expected there is evidence to show that a process of bacterial selection occurs in the fly's intestine. Some bacteria appear to flourish, but others are rapidly eliminated. Among the latter must be numbered B. typhosus."

Relation of the common root maggot (Pegomyia fusciceps) to certain crops in Louisiana, E. S. Tucker (Jour. Econ. Ent., 10 (1917), No. 4, pp. 397-406).—The author reports upon injury in Louisiana to young tomato plants, garden peas, seed potatoes, young corn, and onions, and infestation of cottonseed used for fertilizer, by this root maggot.

A buprestid household insect (Chrysophana placida), H. E. Burke (Jour. Econ. Ent., 10 (1917), No. 4, pp. 406, 407).—The author records the injury to window casings and door frames of sugar pine. (Pinus lambertiana) by this buprestid at Placerville, Cal.

The life history of Diapus furtivus, C. F. C. Beeson (Indian Forest Rec., 6 (1917), No. 1, pp. 29, pls. 2).—This paper reports upon studies of the life history and economic importance of D. furtivus, a species of shot-hole borer which attained notoriety in connection with the death of sal trees in Bengal. This borer is able to kill off trees with diseased roots, but its attack is not fatal to trees weakened by defoliation, creepers, unsuitable local conditions, etc. It normally breeds in newly dead or felled trees and is particularly abundant in felling areas and depots, being active throughout the year.

Its chief economic importance lies in the damage to unbarked timber, which takes the form of shot holes and lines and stained wood defects. It may be controlled by early barking on felling areas and the removal of newly dead trees in other parts of the forest.

The weather and honey production, L. A. Kenoyer (Iowa Sta. Bul. 169 (1917), pp. 15-26, fig. 1).—The author here reports studies, based on daily records for 29 years, kept by a successful beekeeper, as to the weight of a hive of bees and the accompanying weather conditions. These show that changes in the weather exert a marked influence on the production of honey. The conclusions drawn are as follows:

"June yields 56 per cent of the annual hive increase and July about half of the remainder. A large June increase is indicative of a good honey year. There is an evident alternation between good and poor years. A good year has a rainfall slightly above the average, the honey season being preceded by an autumn, winter, and spring with more than the average precipitation. A

rainy May scarcely fails to precede a good honey season. South wind seems favorable and east wind unfavorable.

"The yield shows a gradual depression preceding and a gradual increase until about the fourth day following a rainy day, after which it remains fairly constant until about the fourteenth day following the rain. Good honey months average slightly higher in temperature than poor, this being especially true of the spring and fall months. Clear days are favorable to production of honey. Yield is best on days having a maximum of 80 to 90° F. and a wide daily range of temperature is favorable for a good yield. A low barometer is also favorable for good yield. The fluctuations in yield for a producing period seem to be closely correlated with the temperature range and the barometric pressure, acting jointly. A cold winter has no detrimental effect on the yield of the succeeding season, but a cold March reduces it. A winter of heavy snowfall is in the great majority of cases followed by a larger honey yield."

Seventh annual report of the State inspector of apiaries for the year 1916, B. N. Gates (Mass. Bd. Agr., Apiary Insp. Bul. 11 (1917), pp. 26).—This, the usual annual report (E. S. R., 35, p. 662), is devoted particularly to a discussion of the occurrence of bee diseases in the State, the effect of repellent sprays, etc.

The domestication of the Indian honeybee, L. V. Newton (Agr. Jour. India, 12 (1917), No. 1, pp. 44-57, pls. 5).—This paper relates particularly to Apis indica.

Life history and habits of Polistes metricus, F. C. Pellett (*Proc. Iowa Acad. Sci.*, 23 (1916), pp. 275-284, figs. 2).—A report of observations made in Iowa.

Further observations upon the habits of the western wheat stem sawfly in Manitoba and Saskatchewan, N. CRIDDLE (Agr. Gaz. Canada, 4 (1917), No. 3, pp. 176, 177).—The data here presented which relate to Cephus occidentalis are supplementary to those given in the bulletin previously noted (E. S. R., 34, p. 250).

The author finds that this sawfly is dependent largely on wild grasses, particularly those of the genus Agropyron, including A. richardsoni, A. smithii, and A. repens, for its perpetuation. Various species of lyme grass (Elymus spp.), most of which show a marked preference for deserted fields, roadsides, etc., have proved to be of greater importance as hosts of the sawfly than was thought at first to be the case. Couch grass (A. repens), which grows freely among the various cultivated crops, is probably a greater menace as a host of the sawfly than any of the others. As regards remedial measures, it has been found that a trap strip of rye or wheat sown between the previous season's infestation and the new crop early in the spring and plowed down about the middle of July or cut with a mower at that time may be used to considerable advantage.

An American species of the hymenopterous genus Wesmaelia of Foerster, P. R. Myers (Proc. U. S. Nat. Mus., 53 (1917), pp. 293, 294).

A report on a collection of Hymenoptera (mostly from California) made by W. M. Giffard, S. A. Rohwer (*Proc. U. S. Nat. Mus.*, 53 (1917), pp. 233-249).—This contains descriptions of 15 species new to science.

Australian Hymenoptera Chalcidoidea, A. A. GIRAULT (Mem. Queensland Mus., 5 (1916), pp. 205-230; abs. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 3, p. 129).—Among the parasites here described as new are Pterygogramma acuminata n. g. and n. sp., reared from eggs of a jassid embedded in twigs of Eucalyptus; Alaptus immaturus n. sp., reared from sugar-cane leaves contain-

ing leaf-hopper eggs, but not proved to be parasitic on them; Paranagrus optabilis n. g. and n. sp., reared from eggs of Perkinsiella saccharicida; P. perforator n. sp., reared from the eggs of delphacid leaf-hoppers; Polynema reduvioli n. sp., parasitic in eggs of Reduviolus blackburni in the Hawaiian Islands; Anagrus frequens n. sp., reared from eggs of delphacids; and Paruriella viridis n. sp., reared from the seeds of grass (Panicum sp.).

Parasitism of the larvæ of the Mediterranean fruit fly in Hawaii during 1916, C. E. Pemberton and H. F. Willard ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1915-16, pp. 111-118).—This is a general summary of the fruit-fly parasite situation in 1916.

The four parasites Opius humilis, Diachasma tryoni, D. fullawayi, and Tetrastichus giffardianus, are said to have become established in many localities in the Territory. Summaries are given of the percentage of parasitism of fruit flies infesting various crops, etc., in different localities. The average parasitism as taken from over 26,000 larvæ secured from the kamani nut (Terminalia catappa) was about 41 per cent. It is much higher during some weeks and at other times much lower. The average parasitism in larvæ secured from most other fruits throughout the ripening season was somewhat less than 40 per cent, although coffee was an exception, as the larvæ therefrom were found to be as a rule highly parasitized. There seems to have been very considerable fluctuation in relative abundance of at least three of the established species of fruit fly parasites. Whereas O. humilis spread rapidly in a few months after liberation, it took D. tryoni two years to gain a foothold, but within the four months prior to the preparation of this paper it had almost entirely supplanted O. humilis, particularly in Kona and about Honolulu.

Notes on the construction of the cocoon of Praon, C. N. AINSLIE (Ent. News, 28 (1917), No. 8, pp. 364-367).

An egg parasite of the sumac flea-beetle, C. R. Crosby and M. D. Leonard (Ent. News, 28 (1917), No. 8, p. 368, fig. 1).—A chalcidid parasite reared from the eggs of the sumac flea-beetle (Blepharida rhois) at Norfolk, Va., by L. B. Smith, is described as new under the name Tetrastichus ovipransus.

An aphis parasite feeding at puncture holes made by the ovipositor, L. P. ROCKWOOD (Jour. Econ. Ent., 10 (1917), No. 4, p. 415).—Observations of the feeding of Aphelinus lapisligni n. sp., on the julces of its host (Aphis bakeri) are recorded.

Megastigmus aculeatus introduced into New Jersey from Japan, H. B. Weiss (Jour. Econ. Ent., 10 (1917), No. 4, p. 448).—M. aculeatus, a hymenopteran which destroys the entire interior of seed of Rosa multiflora, appears to have become established in New Jersey and has also been reported as occurring at Ithaca, N. Y.

The embryonic development of Trichogramma evanescens, monembryonic egg parasite of Donacia simplex, J. B. Gatenby (Quart. Jour. Micros. Sci. [London], n. ser., 62 (1917), No. 246, pp. 149-187, pls. 3).—This chalcidid oviposits on the egg mass of a beetle (D. simplex), a single parasite emerging from a host egg, and is also known to parasitize eggs of dragon flies.

Contribution to the life history and habits of the spinose ear tick, Ornithodoros megnini, W. B. Herms (Jour. Econ. Ent., 10 (1917), No. 4, pp. 407-411).—A report of observations of the biology of O. megnini in California, data relating to which species have been previously noted (E. S. R., 27, p. 865).

Tarsonemus pallidus, a pest of geraniums, P. Garman (Maryland Sta. Bul. 208 (1917), pp. 327-342, 19s. 13).—This is a report of studies of the biology of T. pallidus (=T. approximatus), made during the course of an investigation of the cause and method of transmission of the geranium leaf spot, and to which the author gives the name "pallid mite."

The species was first noticed in America in New York in 1898 and described by Banks the following year under the name *T. pallidus*. Previous to that time a similar and apparently identical mite was described from cultivated verbenas in Illinois by Garman, who attributed the spread of a "black rust" to it. In Maryland it is fairly common in greenhouses and a source of injury to cyclamens, chrysanthemums, snapdragons, fuchsias, and geraniums. The author records the discovery of a female of a species of Tarsonemus identical with *T. pallidus* at College Park, Md., on linden trees, indicating that it may not be confined to greenhouses.

The injury to geraniums is sometimes severe, causing the leaves to curl, spot, and drop prematurely. The injury to heavy-wooded varieties is less pronounced. The presence of the mite is often first recognized by the appearance of scorched spots on the underside of the leaves. Cyclamen flowers are also attacked frequently, the flowers withering and curling in much the same manner as the leaves. It is most severe when the plants are crowded, the leaves in contact, and the humidity high. If the plants are well spaced the injury is seldom serious, and the mites disappear or are greatly reduced in numbers in a short time.

The eggs, which are laid during the night on the underside of the leaf or in a protected spot between the leaf and the main stem, were found to require from 3 to 7 days for incubation at a temperature of from 68 to 77° F. larval stage of the female is divided into two periods, the first consisting of an active period lasting 1.5 to 3 days and the second a quiescent or inactive period lasting from 1 to 3 days. At the end of the quiescent period the insect molts and the adult mite emerges, oviposition commencing in about 2 days, The life cycle of a single reared male required 5 days for the egg. 2 days for active larva, 3 days for quiescent larva, and 6 days for the adult, or a total of 16 days. The species was found to be parthenogenetic, continuous generations being obtained, starting with a single egg or larva confined in glass cells, which lived more than five months without the appearance of the male. Its capacity to reproduce parthenogenetically is continued for at least three generations and probably more. In regard to the rate of reproduction the author concludes that with a minimum oviposition of one egg per day during the egg-laying period and a maximum of 12 eggs per female the number of individuals should total 40 at the end of one month, provided no males appear. His method of rearing the mites consisted in the use of shallow concave cells provided with a small square of lens paper and a piece of geranium leaf. Farrant's medium proved to be the best for mounting specimens,

Tests of the effect of various insecticides on *T. pallidus* are reported in tabular form. Those tested and discarded because of injury to geranium foliage include lime-sulphur 1:40 and 1:50, turkey red oil 1:30, carbon disulphid emulsions 0.5 to 5 per cent (with liquid soap), sodium fluorid, sodium chlorid 10 per cent solution, kerosene emulsion, and Tak-a-nap soap 1 lb. to 20 gal. Injury from chromic and picric acids is slow in appearing, and it is possible that a thorough watering of the plants on the day following treatment will reduce injury to a negligible factor. Small tests with blackleaf 40 seem unfavorable on the whole, but it is thought probable that nicotin has some repellent action and should prove valuable as a preventive. A stream of water will dislodge this mite more readily than it will red spider, due to the absence of webs. With geraniums the use of a stream of water as a control is available because the leaves do not curl sufficiently to hide the mite as is the case with snapdragons.

The cyclamen mite, G. F. Moznette (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 8, pp. 373-390, pls. 2, figs. 6).—This is a report of studies of the

biology of Tarsonemus pallidus, made in a badly infested greenhouse at the Oregon Experiment Station.

This species is a very serious floral pest found as far east as Connecticut, and is thought to occur throughout the United States wherever cyclamen stock is grown. In greenhouses in Washington and Oregon in several cases growers lost their entire stock of cyclamen during 1916 and it has been reported to injure seriously chrysanthemums and snapdragons. The distortion of the leaves and the discoloration of the flowers are the most noticeable effects of its attacks. The work of the mite resembles a gall on the older leaves as well as on the young, developing leaves, but the older leaves are not generally attacked. The continued growth of the damaged parts results in distortion of the leaves, giving the plants a very dwarfed and shriveled appearance. Often the leaves become very much thickened at the points immediately surrounding the injured parts. When the infestation is severe, the plants appear ultimately so badly curled and distorted as to be unsalable and they do not bloom normally. This mite is supposed to be spread by the shipment of seedlings and specimen plants from one place to another.

Technical descriptions are given of its several stages. In life history studies no nymphal stage was found, the larva transforming to a quiescent stage from which the adult emerges. Oviposition took place over a long period, the eggs being found from early November until the last of March. The eggs are laid in masses in moist, dark places provided by the curling and distortion of the leaves of the cyclamen plant. The average length of the incubation period of ten eggs at a temperature of about 70° was about 11 days. The average larval period for 10 individuals for the active stage was about 7 days, the larvæ being found from November to the last of March. The length of the quiescent stage averaged 3.5 days for 10 specimens. The adults are present from November until late spring, and it is thought that they may be found in the greenhouse throughout the year. The rearing methods employed are briefly described.

In discussing remedial measures it is pointed out that owing to the mites having an extremely primitive respiratory system fumigation is an unsatisfactory measure and spraying must be resorted to. After the older plants become badly infested there is not much hope of saving them as the mites are usually concealed under the calyx and penetrate even to the inner flower parts of the buds so that it is quite impossible to reach them, and it is advisable to burn the plants and sterilize the soil. The stable nicotin extracts and the volatile nicotin extracts, as blackleaf 40, are practically identical so far as killing properties are concerned, and used at the rate of 1:1,000 appear to be the most satisfactory means of control. The application of the nicotin spray containing a small quantity of soap should be started when the plants are quite young and continued every 10 days until the flower buds are well developed and begin to show color.

A list of 12 references to the literature is appended.

A synopsis of the genera of beetle mites with special reference to the North American fauna, H. E. Ewing (Ann. Ent. Soc. Amer., 10 (1917), No. 2, pp. 117-132, figs. 6).—In addition to keys to the families, subfamilies, and genera of Oribatoidea descriptions are given of 12 new genera.

On the nymph and prosopon of the tsutsugamushi, Leptotrombidium akamushi n. g. (Trombidium akamushi Brumpt), carrier of the tsutsugamushi disease, M. Nagayo, Y. Miyagawa, T. Mitamuba, and A. Imamuba (Jour. Expt. Med., 25 (1917), No. 2, pp. 255-272, pls. 4).—The mite here dealt with is the carrier of the tsutsugamushi or kedani disease, an acute exanthematous infectious disease which up to the present occurs only in the northern coast districts of Japan and in Formosa. The mortality from this disease, which closely

resembles Rocky Mountain spotted fever, varies from 20 to 50 per cent. In this paper the authors deal at length with the morphology and biology of the mite, for which they suggest the generic name Leptotrombidium. A bibliography of 16 titles is included.

Is Trombidium holosericeum the parent of Leptus autumnalis? M. Nagayo, Y. Miyagawa, T. Mitamura, and A. Imamura (Jour. Expt. Med., 25 (1917), No. 2, pp. 273-276, pl. 1).—While the tsutsugamushi, Leptotrombidium (Trombidium) akamushi, is almost identical with the European L. autumnalis, the authors' observations and study of the literature failed to convince them that T. holosericeum is the parent of L. autumnalis. Regarding the host relations of L. autumnalis the authors state that "there is perhaps no mammal, which comes within their reach, unmolested by them; they have been found on hares, rabbits, various kinds of mice, badgers, hedgehogs, molebat, shrew, dogs, and cats. On birds, reptiles, insects, and spiders I could, however, not effect any infestation, though on insects and spiders near relations of L. autumnalis parasitize. Our tsutsugamushi attacks field mice, rabbits, guinea pigs, monkeys, and other mammals, but not insects."

Notes on parasitic acari, S. Hirst (Jour. Zool. Research, 1 (1916), No. 2, pp. 59-81, figs. 14).—These notes relate to some species of acari parasitic on mammals and birds in Great Britain and include descriptions of two new African mites of the family Gamasidæ. Keys are given to the species of the genera Haemogamasus, Dermanyssus, and Laelaps occurring in Great Britain.

The chicken mite: Its life history and habits, H. P. Wood (U. S. Dept. Agr. Bul. 553 (1917), pp. 14, pl. 1, figs. 2).—This is a report of studies made at Dallas, Tex., of the main points in the life history and bionomics of Dermanyssus gallinæ, especially those of importance in the application of control measures.

The incubation period of the eggs during the latter part of August at an average mean temperature of 78.43° F. was about 48 hours. At an average mean temperature of 73.5° the larva molts in about 24.5 hours without ever having fed. At an average mean temperature of 82.9° the first stage nymphs molt in somewhat less than 24 hours. With the exception of one individual observed the second stage nymphs molted to adults in 3 days after feeding. Fertilization normally takes place off the host and usually before feeding, followed by oviposition within about 12 hours after feeding. Females deposit an average of 4 eggs each at the rate of 4 eggs in 24 hours and they will continue to feed and deposit at least eight times with one fertilization.

The details presented relating to the life cycle show 10 days to have been the actual time taken to pass through the life cycle under favorable conditions, but under natural conditions it is thought that the period would be reduced in August to at least 8.5 days. A certain amount of moisture and a moderate temperature were found to favor longevity, while extreme dryness and high temperatures are unfavorable factors. Under favorable conditions during July, August, September, and October, adults and second stage nymphs lived from 91 to 98 days. The longest period for adults which had never fed was 88 to 96 days during October, November, December, and January. The longevity of the first stage nymphs was found to be about the same as the other stages. During the months of September to January, inclusive, all stages on wood lived from 91 to 113 days, while stages in a glass chimney with a cracked egg lived more than 107 days during the same months. The conclusions drawn from these observations are that the mite can be starved out of a chicken house by keeping fowls and other animals away from the house for four months during the summer season and for 5 months during the cooler season in the latitude of Dallas, Tex.

It was found that normal feeding takes place during the hours of darkness and that the mites leave the fowl soon after feeding, all stages attaching to, feeding, and leaving a fowl in less than 2 hours. It is pointed out that dispersion of the mites may take place by infested fowls being transferred to clean localities, by the use of boxes and crates in which infested fowls have been kept, through being carried by man on his clothing, on sparrows, pigeons, horses, cattle, dogs, cats, and certain wild animals, such as foxes, skunks, and weasels, and by migration of the mites to buildings in contact or close proximity to infested premises. Since the mites prefer to hide on roosts or adjacent thereto, the roosts should not be attached to the walls.

For control measures the author refers to Farmers' Bulletin 801, previously noted (E. S. R., 37, p. 357). The natural enemies mentioned include a small black ant (Monomorium minimum), the fire ant (Solenopsis geminata), and spiders.

New mites, mostly economic, N. Banks (Ent. News, 28 (1917), No. 5, pp. 198-199, pls. 2).

# FOODS-HUMAN NUTRITION.

A comparison of several classes of American wheats and a consideration of some factors influencing quality, L. M. Thomas (U. S. Dept. Agr. Bul. 557 (1917), pp. 1-28, figs. 21).—From milling and baking tests undertaken in cooperation with the North Dakota Experiment Station with a view to procuring data of value in establishing a scientific basis for the classification and grading of wheat, the following conclusions were drawn:

"Normal, plump, dry, and sound wheat of all classes yields approximately the same percentage of flour. Over 80 per cent of the samples of each of the three classes of the more common wheats, soft and hard red winter and hard red spring, yielded between 67 and 75 per cent of flour.

"There is a direct relation between milling yield and the moisture content of wheat, and in a general way the yield varies inversely with the moisture content. . . .

"The weight per 1,000 kernels or average weight of kernels has very little value in judging the potential flour yield.

"Although there are frequent exceptions when individual samples are considered, average results show a very striking relation between weight per bushel and flour yield, the latter varying directly as the former. The ratio between these two figures, however, is not quite the same for the different classes, nor is it the same for all varieties within each class.

"In color the bread from the flour of the various classes of common wheat shows about the same ranges and averages. The flour from durum wheat is considerably more creamy and thus averages several points lower than that of any other class. Bread from all normal durum samples has a tinting or coloration varying from slightly creamy to bright yellow, while of the hard red winter samples 77.6 per cent show a noticeable creamy tint; of the hard red spring samples, 69.5 per cent; and of the soft red winter samples, only 18.9 per cent.

"The general results indicate that test weight and soundness, considered together, are of far more value in appraising quality than any one of them considered by itself.

"Small amounts of inseparable material are generally accompanied by a decrease in flour yield, as would be expected, in that as a rule a large part of such material usually finds its way into the bran and shorts.

"Loaf volume and texture are the two factors which are considered as indicative of strength. While a great range of strength was found within each

class of wheat, the averages for each class show considerable differences between the various classes when considered as a whole. Given in order from weakest to strongest, the classes are soft white, soft red winter, durum, hard red winter, and hard red spring wheat.

"The average loaf volume in cubic centimeters for each of these classes is soft white wheat, 1,909; soft red winter, 1,965; durum, 2,070; hard red winter, 2,219; and hard red spring, 2,421. In the matter of texture the several classes stand in the same order, except that soft red winter has a slight advantage over durum wheat.

"Of the four more important classes of wheat under consideration, durum is the highest in crude-protein content; hard red spring, second; hard red winter, third; and soft red winter, fourth. High crude-protein content as a rule is accompanied by high strength, but the relation between these two factors varies with the different classes of wheat and extremely high crude-protein content is sometimes accompanied by a decrease in baking strength.

"The average water absorption of the flour from durum and from hard red spring wheat is about the same, and that of hard red winter is only slightly lower. The water absorption of the soft wheats averages from 3 to 4 per cent lower than for the hard wheats. The range of water absorption of each class varies within wide limits. There is a direct relation between the water absorption of the flour and the bread yield of a unit quantity of the same. As a rule, the higher the absorption the greater the weight of the loaf."

Wheat and flour investigations, V, G. A. OLSON (Washington Sta. Bul. 144 (1917), pp. 12-86, figs. 14).—Cintinuing previous work (E. S. R., 26, p. 738), two of the three studies reported had to do with the baking quality of flour and the third with the milling value of water-soaked wheat.

In the first study a comparison of the results of the chemical and baking tests of flours from 12 States included offer evidence for the belief that there is no relation between the quality of flour and the total nitrogen, alcoholsoluble protein components, gluten content, water-soluble solids, and acidity. "Neither were relations between the gluten content and the water-retaining qualities of flour observed."

"Although no conclusions could be drawn, the volumes of the loaves appeared to be inversely proportional to the gluten content. A loaf of bread having an apparent specific gravity 0.25 or less may be regarded as a satisfactorily baked loaf."

With respect to the influence upon the baking quality of the removal from flour of water-soluble, alcohol-soluble, and salt-free extracts, and of the addition to flour of electrolytes, the following conclusions from the data are reported:

"The irregularities noted in the nitrogen-free and ash-free extract content of flours giving the same and different volume capacities indicate that the nitrogen-free and ash-free extracts do not bear the relation to volume that would be expected according to theory.

"There is strong evidence supporting Wood's theory that the ratio of soluble ash to total nitrogen determines the shape of the loaf. Our experiments indicate that the nature of the electrolytes contained in the soluble ash may have something to do with the property of shape, and this may account for the irregularities noted.

"The baking quality of flour was not perceptibly affected by the addition of lactic acid at the rate of 0.54 gm. per 100 gm. of flour; the addition of the mentioned amount of acid, however, did affect the amount of gluten that could be separated from the flour. The significance of modifying the quality of the gluten and its unnoticeable effect upon baking quality should not be overlooked.

"The removal of the 70 per cent alcohol extractives from flour impaired the baking qualities of the flour to the extent that it was impossible to obtain a satisfactory fermentation of the dough.

"Flour in which a part of the soluble salts had been removed through the process of dialysis also gave unsatisfactory fermentation action when compared with the same flour untreated."

The second of the studies has to do with the influence of the various components of flour upon baking quality and is a progress report. Some of the results obtained are summarized as follows:

"The water-soluble extractives from flour were added to both wheat and corn starch with beneficial results in volume production. Flour from which the gluten was removed gave similar results.

"The addition of gluten to both wheat and corn starch resulted in forming compact, rubbery masses. Flour from which the water-soluble extractives were removed also resulted in forming compact masses.

"The addition of the water-soluble extractives to flour made up of either wheat starch and gluten, or cornstarch and gluten, resulted in increased volumes, but these were not equal to the volumes obtained by mixing the water-soluble extractives with both the wheat starch and cornstarch or flour from which the gluten had been removed.

"While it is true that the significance of the water-soluble and gluten component of flour to baking quality are shown to a certain extent in our experiments it is impossible at this writing to express the exact importance of each."

The results obtained in the study of the milling value of water-soaked wheat are summarized as follows:

"Wheat which has been allowed to sprout loses in weight as the length of time allowed for germination advances. The milling value of germinated wheat decreases as the length of the plumule increases. The length of time required for the conversion of starch decreases as the length of the plumule increases, to at least twice the length of the kernel.

"The amount of gluten which can be recovered from flour from germinated wheat is less than that from ungerminated wheat. The yield of gluten decreases rapidly as the plumule increases in length.

"Expressed in percentage of total nitrogen, the alcohol-soluble nitrogen has been affected by the germination of wheat. The most marked changes were observed in the glutenin and amid nitrogen. In the former there was a sudden decrease in amount from the period where the plumule was equal to the length of the kernel to that where the plumule was equal to twice the length of the kernel. The amid nitrogen increased rapidly from the time when the plumule was equal to the length of the kernel.

"When germinated wheat flour was baked only the quality of the crumb of the bread was impaired; this was particularly noticeable in flours made from germinated wheat in which the plumule was equal to or twice the length of the kernel. The volume of the loaf increased, being exceptionally large in the bread made from partially germinated wheat flour.

"Using small quantities of germinated wheat flour with other flour, it was found that the volume of the loaf could be increased without impairing the texture of the loaf. Each particular flour requires a different amount of germinated flour in order to produce the best results. Too large an amount of strongly diastatic flour is less beneficial than none.

"A water-soaked wheat is not necessarily spoiled and can be used for milling purposes, providing it has been thoroughly cleaned and dried."

The introduction to the bulletin summarizes historical data, which are supplemented by a bibliography.

The milling and baking data for the 1915 crop of wheat, T. Sanderson (North Dakota Sta. Bul. 122 (1917), pp. 61-94).—This includes a critical discussion of wheat grading and its effect upon the economies of the wheat industry from an agricultural standpoint. It is based upon milling and baking tests reported for a large number of wheats.

"Summing up this whole matter as to the trouble resulting from the sale of wheat it may be safely charged to the system used in grading. . . . It is evident that the majority of men engaged in the grain trade are not aware of the true milling value of the different lots of wheat coming to them and that they are conscientious in their application of the system in vogue, while it is the strict application of this system that is working such a hardshp on our local miller, as well as the farmers. If the local millers were aware of the actual value of the so-called lower grades of wheat, they would use more of them in their mixture, thus reducing the cost of their raw material. At the same time they would reduce the amount of low-grade wheat going to the terminal market; thereby increasing the cost of the raw material to their competitors."

"There is some wheat in almost every crop year that should not be used for human consumption, but should be condemned and only allowed to be sold as animal food, and if not fit for that prupose, should not be allowed on the market at any price, the same as is done with meat and many other food products, but under the present system the majority of this low-grade wheat is bought by the elevator companies and mixed in small quantities and eventually finds its way into the flour of the consumer. In many instances the price paid is far below what it is actually worth for feed. Many of the complaints from the consumers coming to the miller are just and could be attributed to this cause."

Similar data for other years have been noted (E. S. R., 34, p. 759; 36, p. 464). Shrimp: Handling, transportation, and uses, E. D. CLARK, L. MACNAUGHTON, and MARY E. PENNINGTON (U. S. Dept. Agr. Bul. 538 (1917), pp. 1-8, pls. 2).—Handling, preparing, and shipping cooked and raw shrimps, dried shrimps, and other specialties, the utilization of shrimp waste as fertilizer, and the food value of shrimp meat are discussed in this bulletin, the data including analyses of cooked, canned, and dried shrimps.

"Cleanliness, proper cooking, and care in handling shrimp, combined with a discontinuance of the practice of using preservatives, have resulted in the production of a finely flavored product which is gradually increasing in popularity. At the same time improvements in methods of packing and preparation have made shrimp accessible to many new markets at long distances from the producing sections. . . .

"The increased consumption of shrimp and the opening of new markets are stimulating the industry to increase its catches. If shrimp are taken at the wrong time of year or in excessive numbers their extermination is probable. Those interested in the shrimp industry, therefore, should give early attention to the question of conservation. It is also to the interest of those whose livelihood is dependent upon catching and packing shrimp to encourage investigations planned to determine the periods of spawning, the times of migration, and the feeding habits of shrimp, and to do their part in helping to make such investigations result in the adoption of protective measures."

Food products and drugs, J. P. Street (Connecticut State Sta. Rpt. 1916, pt. 4, pp. 185-304).—The 1,369 products here reported on include, among many others "hygienic coffees," diabetic foods, condensed and powdered milks, spices, vegetable extracts, baking powder, spices, and a proprietary article akin to meat extract made from squab.

[Food and drug inspection], E. F. LADD and ALMA K. JOHNSON (North Dakota Sta. Spec. Bul., 4 (1917), No. 14, pp. 363-378).—In addition to data re-

garding sanitary inspection and the examination of foods and beverages, information is given on a proprietary drug preparation by C. P. Guthrie, and on Stealing Bread and Butter, by R. E. Remmington, is included, the latter having to do with "a very general sale of short-weight butter" which "inspectors of the food department have discovered."

How to select foods.—III, Foods rich in protein, Caroline L. Hunt and Helen W. Atwater (U. S. Dept. Agr., Farmers' Bul. 824 (1917), pp. 2-19, figs. 2).—In this, the third of the series (E. S. R., 37, p. 668), the proper selection of foods rich in protein is discussed in relation to the other four food groups into which foods may be conveniently divided for the discussion of dietary problems.

"Since the protein foods include many of the more expensive foods in common use, and since an adequate supply of protein is essential to the growth and upkeep of the body, it is especially important for the housekeeper to know how much her family needs and to be able to choose the materials which, in her particular circumstances, will best provide the proper kind and amount."

Among the generalizations made are the following: "The foods usually classed as rich in protein are: Milk and cheese; eggs; meat, poultry, and fish; dried legumes, such as peas, beans, cowpeas, soy beans, and peanuts; and almond and some other nuts. Wheat, oats, and some other cereals also furnish considerable amounts of protein. Milk is the best source of protein for children. There is about one-fourth ounce of protein in each of the following: One glass of milk, one egg, 1½ to 2 ounces of meat, 1 ounce of cheese, and 13 ounces of bread." "A man at moderate muscular work is believed to need about 3½ oz. of protein a day, and a family consisting of father, mother, and three small children about 12 oz. a day."

"It is possible to plan an attractive and wholesome diet in which one-half of the necessary protein is supplied by bread and other cereal foods which are relatively cheap. The more milk, eggs, and other protein-rich foods are combined with other foods in cooking, the less protein-rich foods are needed for use as separate dishes. Skim milk is not a substitute for whole milk as a food for little children, but it can be so used as a source of protein in the diet of adults. A quart in cooking or to drink will add as much wholesome protein to the general diet as a quart of whole milk. Providing they are clean and wholesome, sour skim milk and buttermilk may be used instead of sweet. Real economy in the use of protein foods lies not in leaving them out of the diet, but in choosing and combining kinds which will supply the total amount needed as cheaply as circumstances permit."

## ANIMAL PRODUCTION.

A quantitative comparison of casein, lactalbumin, and edestin for growth or maintenance, T. B. Osborne, L. B. Mendel, et al. (Jour. Biol. Chem., 26 (1916), No. 1, pp. 1-23, figs. 4).—To avoid criticisms made in the case of previous experiments when food was given ad libitum, in this case the animals were fed equal amounts of the isolated food materials. By keeping the food below the amount ordinarily consumed and varying the amount from day to day the animals were kept growing at nearly the same rate.

The results of the test show that with rats of similar initial weights and with the same amount of food in equal portions daily, the lactalbumin foods in every case gave the largest gains. These later experiments prove also what was formerly indicated, namely, that the comparative inferiority of casein may be corrected by the addition of the essential amino-acid cystin. The experiments further show that protein beyond a concentration of approximately 12.5 per cent of the total calories failed to give increase of body weight.

In a second experiment instead of giving each animal equal amounts of food daily it was increased to each individual in proportion to the gains made. Lac-

talbumin again was superior, it taking 50 per cent more of casein and nearly 90 per cent more edestin to produce the same gain. With a lactalbumin food containing 8 per cent it took 12 per cent of casein and 15 per cent of edestin to produce the same gain in weight. The replacement of cystin by alanin in the ration with casein failed to bring about a nutritive advantage. In mature animals where maintenance requirements and not growth are to be met, the results with the different proteins are not so marked.

Further experiments were made in which the three proteins were fed daily in such a way that no essential gain or loss in body weight occurred. The total energy intake was made sufficiently liberal, the protein only being kept at the minimum. The results corroborate the former conclusions as to the comparative superiority of lactalbumin when fed with the other two proteins in minimum amounts.

The effect of the amino acid content of the diet on the growth of chickens, T. B. Osborne, L. B. Mendel, et al. (Jour. Biol. Chem., 26 (1916), No. 2, pp. 293-300, pl. 1).—Experiments by the authors with rats have shown the importance of certain amino acids for growth, notably tryptophane, lysin, and cystin. Similar work by Buckner. Nollau, and Kastle (E. S. R., 34, p. 871) with chickens is noted. Further work was carried on with chickens, using foods similar to those employed with rats.

The results with chickens were found in accord with those obtained in the experiment with rats. Lactalbumin, rich in both tryptophane and lysin, proved to be an efficient adjunct to the proteins of corn gluten.

The productive values of some Texas feeding stuffs, G. S. Fraps (*Texas Sta. Bul. 203 (1916*), pp. 5-42).—These experiments were conducted in the same manner as those previously noted (E. S. R., 27, p. 668; 31, p. 862). The coefficients of digestibility and productive values as determined on sheep are shown in the following table:

Average coefficients of digestibility of feeding stuffs and productive values.

Live stock feeding experiments (Dept. Agr. and Tech. Instr. Ireland Jour., 16 (1916), No. 3, pp. 418-430).—The report deals with experiments carried out during two years, 1913-1915, under the supervision of agricultural instructors in almost every county in Ireland. The following conclusions are drawn:

In pig feeding raw meal showed a saving in fuel and labor. Cooking failed to give returns either in amount of feed consumed, length of fattening period, or quality of the pork.

In calf feeding maize meal with separated milk showed practically as good results as a calf meal made up of 1 part ground flaxseed, 2 parts maize meal, and 2 parts oatmeal.

With cattle the feeding of a mixture of 2 parts undecorticated cotton cake and 1 part maize meal on second-rate pasture did not give a profitable increase in live weight. Indirectly it might give a profit by earlier maturity or better appearance at marketing.

With stall-fed cattle the extent to which turnips should be used is deemed a question for each farmer to decide. In most cases it seemed sound economy to grow them extensively and feed liberally. Cattle can be fattened successfully with 3 stone (42 lbs.) of turnips per head daily.

Almost similar results were obtained with two rations, one with 84 lbs. of roots and a moderate amount of concentrated food, and one of 42 lbs. of roots and an extra allowance (3 lbs.) of concentrated food.

Color inheritance in mammals, S. WRIGHT (Jour. Heredity, 8 (1917), No. 5, pp. 224-235, figs. 2).—An attempt is here made to relate the biochemical findings in regard to melanin with color relations that have come to light in genetic work. A scheme is proposed for showing the interrelations of the different mammalian coat colors, and a classification of color factors is suggested.

The value of good sires, J. K. Wright (Missouri Bd. Agr. Mo. Bul., 14 (1916), No. 9, pp. 5-86, flgs. 58).—This bulletin reviews in a general way the principles of heredity, environment, and variation, and shows by citation of a few great herds and from experimental data from other sources the value of good sires in the improvement of horses, asses, cattle, sheep, and swine.

The heredity of dual-purpose cattle, H. F. Euren (Norwich, [England]: A. D. Euren, 1917, pp. 96).—A brief history is given of the origin and development of the dual-purpose Red Polled breed of cattle, including an account of the work of John Reeve, of Wheycurd Hall Farm, Wighton, England, and others in the development of the breed.

For the study of the heredity of the Red Polled, as evidenced by its milk production and its beef production, the author has prepared from the British and American Herd Books the extended pedigree of 29 cows in the United Kingdom and of 11 in the United States. In each of the pedigrees has been worked out the percentage of blood of polled "home-bred" cattle of Norfolk, polled Suffolk, and the Reeve blood-red breed.

Details are given of the breeding of noteworthy bulls that have been used in developing the Red Polled dual purpose cattle, together with data on the cost of feeding for milk and beef. Transcripts are also given from the British and American Herd Books showing the butter production and beef-making qualities of some of the leading strains and families of Red Polled cattle.

Sheep breeding and feeding, J. M. Jones (Texas Sta. Bul. 205 (1917), pp. 3-24, figs. 5).—The object of this test was to determine which of the most common mutton breeds of rams when crossed with fine-wooled ewes would produce the most thrifty and desirable lambs grown and fattened under Texas conditions.

Good Rambouillet range ewes of uniform type and breeding were used, 148 ewes being divided into six lots and bred to rams as follows: Lot 1, Rambouil-

let; lot 2, Shropshire; lot 3, Hampshire; lot 4, Southdown; lot 5, Lincoln; and lot 6, half-blood Karakule-Lincoln. The resulting lambs numbered 120, all of which were hardy and thrifty from birth. The highest average birth weight was shown by the Hampshire-Rambouillet cross, and they also made the greatest total gain and seemed to finish in a shorter period. The cost of feed per pound of gain in the experiment was, from October 13 to January 5, 3.32 cts., and from January 6 to 17, 5.03 cts.

Six of the best lambs were taken from each lot and fed from January 6 to March 8 for the National Feeders' and Breeders' Show. The cost of feed per pound of gain during this period was 6.32 cts. Pens of these lambs in competition at the show were ranked as follows: Lincoln-Rambouillet, Hampshire-Rambouillet, Southdown-Rambouillet, Rambouillet, Karakule-Rambouillet, and Shropshire-Rambouillet.

A novel salt trough used during the experiment, and which seemed to be effective, was made to apply pine tar to the lambs to keep the gadfly away from the nasal cavities. The trough, 4 in. by 6 in. by 4 ft., had a board  $3\frac{1}{2}$  in. wide placed 3 in. from the bottom. A strip of sheepskin, with the wool side out, was tacked to the edge of this board and smeared with pine tar every evening just before bringing the sheep into the lot.

Oestrus and ovulation in swine, G. W. Corner and A. E. Amsbaugh (Abs. in Anat. Rec., 11 (1917), No. 6, p. 345).—The authors found that animals killed during the period of heat usually show ruptured Graafian follicles, and in such animals the ova were recovered by washing out the Fallopian tubes. Rupture of the follicle is spontaneous, occurring even in the absence of the boar. Sows killed on the third day of heat showed regularly that ovulation had taken place. The unfertilized ripe ovum of the sow, as found in the tube, measures from 155 to 165  $\mu$  in diameter. The zona pellucida is from 7 to 8  $\mu$  thick, inclosing a yolk heavily laden with fat globules, obscuring the nucleus. The polar bodies are often clearly seen in the fresh ovum. Study of a small series of ova which have been cut into serial sections seems to show no deviation from the stages reported in other mammals. The first polar body is formed within the follicle just before rupture, the second in the tube. Entrance of the spermatozoön and fusion of the pronuclei occur in the tube.

Cost of keeping farm horses and cost of horse labor, M. R. COOPER (U. S. Dept. Agr. Bul. 560 (1917), pp. 22, figs. 5).—Results are given of a study of cost accounting records for 154 horses on ten farms in Illinois, 72 horses on seven farms in Ohio, and 90 horses on ten farms in New York. The purpose of the bulletin is to show how the annual cost of keeping a farm work horse and the cost per hour worked may be determined, and to point out that the cost per hour worked is the true measure of the profitableness of a horse to its owner.

The several items of cost and credit which make up the annual average cost per horse are analyzed in detail and tabulated. It was found that the annual net cost for keeping a horse was \$100.65 in Illinois, \$120.37 in Ohio, and \$145.02 in New York. A study of the relation of work performed to the total feed cost shows that on an average on the farms studied there was a fairly uniform difference between the average feed cost and the total cost per hour of horse labor, showing that the number of hours worked and the feed cost per horse are the controlling factors in the total cost per hour of horse labor. Or the Illinois farms the horses worked an average of 1,053 hours per year at an average cost of 9.56 cts. per hour, on the Ohio farms an average of 866 hours per year at an average cost of 13.9 cts. per hour, and on the New York farms an average of 1,020 hours at an average cost of 14.22 cts. per hour.

It was found that the large farms permit of a more efficient use of horse labor than do the small farms. On the large farms in Illinois there were 22.2

acres in crops per horse, while on the small farms there were but 16.8 acres per horse. Similar results were found on both the Ohio and the New York farms, though in these States the difference between the two groups was not as great as in Illinois.

Some important essentials in profitable horse production, C. W. McCampbell (Kansas Sta. Insp. Circ. 2 (1916), pp. 3).—In addition to brief notes on profitable horse production, a list is given of stallions licensed in Allen County during the year ended October 1, 1916. Similar lists are published for all the other counties of the State, each list being issued as Inspection Circular 2.

The theory of sex as stated in terms of results of studies on the pigeon, O. Riddle (Abs. in Anat. Rec., 11 (1917), No. 6, p. 510).—Studies on sex control in pigeons have indicated the nature of the initial difference between germs of prospectively different sex-value. "This difference rests upon different levels of metabolism, and when the metabolic level of a given germ is shifted from the level characteristic of the germ of one sex sufficiently toward the level of the other sex, it develops into an organism of the sex which corresponds to the acquired, or later, level. The initial difference characteristic of the two kinds of (sex) germs, tends to persist and characterize the adults of the two sexes.

"Sex is based on a quantitative difference. Intermediates of the normal extremes have been experimentally produced, and the normal extremes have themselves been experimentally accentuated."

Factors influencing the sex ratio in the domestic fowl, R. Pearl (Science, n. ser., 46 (1917), No. 1183, p. 220).—In this paper on the sex production question in the common fowl, results are given of eight years' experimentation at the Maine Station in which over 22,000 individuals were involved.

This work indicates first that the determination of sex in poultry is primarily a matter of a definite, hereditary mechanism, just as it is in insects and other forms which have been studied. At the same time, it is demonstrated that under certain physiological circumstances the operation of this mechanism may be modified in such a way as to lead to the production of more females in proportion to the number of males. The chief factor in bringing about the modification in the direction of a larger production of females is the fecundity or laying ability of the hens used as breeders. The larger the number of eggs which a hen lays before being put into the breeding pen, the larger will be the proportion of females and the smaller the proportion of males produced by her eggs.

Crossing over in the sex chromosome of the male fowl, H. D. Goodale (Science, n. ser., 46 (1917), No. 1183, p. 213).—In studying sex linkage in fowls, crossing over in the sex chromosomes of the male was seen to have occurred. This preliminary report deals only with the factors themselves, without regard to the somatic appearances of the individuals. "Three dominant sex-linked characters, namely, B, I, and S, were employed. B and I were introduced on one side, S on the other. Hence the F<sub>1</sub> males were all BI, S; B and I being in paternal (or maternal) sex chromosome, S in the maternal (or paternal). These males have been tested by mating them back to females of the composition b Is, b is.

"If there were no crossing over, offspring of this back cross showing the combination of somatic characters found in the F<sub>1</sub> male would not occur. Actually, however, they do occur, thus demonstrating that crossing over has occurred, a chromosome having the composition B I S having been formed. Other cross over classes have appeared, but the one cited is the one at the present age of the chicks most easily recognized."

Further data on the relation between the gonads and the some of some domestic birds, H. D. Goodale (Abs. in Anat. Rec., 11 (1917), No. 6, pp. 512-514).—Published data on the ablation of the testes and ovaries of domestic

birds, together with unpublished data on the transplantation of the ovary into castrated males, tend to show that different parts of the soma react in different ways to the secretion of the gonads. Each character appears to be more or less independent of every other character, just as they are in heredity. The characters affected are (1) those including some of the secondary sexual characters that are independent of either ovary or testis, such as size in the female, voice and some phases of behavior, and mandible color in ducks; (2) those affected by the testis, such as comb and wattles, fat deposition, size in the male, and some instincts and summer plumage in ducks; and (3) those that are affected by the ovary, such as plumage form and color and some phases of behavior.

"If the entire series of altered individuals is examined, it is apparent that it may be looked upon as a series of sex intergrades. That is, characters that are normally found in one sex may be experimentally transferred to the opposite sex while individuals composed of mixtures of such characters may be obtained."

Determinate and indeterminate laying cycles in birds, L. J. Cole (Abs. in Anat. Rec., 11 (1917), No. 6, pp. 504, 505).—The author has noted two distinct types of laying cycles in birds, one in which the number of eggs which will be laid in the clutch is definitely determined when laying begins, and the other in which the number of eggs that will be laid depends upon stimuli received after laying has begun. In other words, the stimulus for cessation of laying and inception of brooding has already been received and the reaction predetermined in the first case, while in the second the stimulus is received later and is followed by cessation of liberation of ova from the ovary, though laying continues for a time afterwards until the ova already discharged have received albumin and shells and have been expelled. The most important stimulus for the onset of broodiness and the consequent cessation of laying in the second class of cases is probably a physiological reaction of the female to a number of eggs in the nest. As a consequence, if the eggs are removed as laid the stimulus does not occur and laying continues beyond the regular clutch to an indefinite number.

Among domesticated birds the pigeon may be taken as an example of the determinate type and the common fowl of the indeterminate. Among wild birds experiments have been carried on with the English sparrow and the house wren, which also appear to represent the two types respectively.

A study of broodiness in the Rhode Island Red breed of domestic fowl, H. D. Goodale (Abs. in Anat. Rec., 11 (1917), No. 6, pp. 533, 534).—In addition to results already noted (E. S. R., 36, p. 173), the author points out that the length of the period before the first broody period appears in Rhode Island Red hens may vary from a month up to two or even more years, while a very small percentage have never exhibited signs of broodiness. Ninety-five per cent, however, of the birds go broody before July 1 of their pullet year. The number of broody periods depends in part on the date of the first broody period and in part on the time the bird stops laying in the fall, and may vary from one to eleven times during the first year. In the second year broody periods begin as soon as the bird lays a comparatively few eggs.

Breeding for egg production.—II, Seasonal distribution of egg production, E. D. Ball and B. Alder (Utah Sta. Bul. 149 (1917). pp. 3-71, figs. 29).—In continuation of previous data (E. S. R., 37, p. 369), this is a discussion of the seasonal distribution of egg production during the first, second, third, and later years of egg laying of the same flocks of hens, and a comparison of the distribution of production of high-laying and low-laying flocks in the same season and different seasons, as well as of high-laying and low-laying individuals

of the same flocks. These studies are based on six flocks of White Leghorn hens ranging from nine to three years old and all descendants of a common flock.

The authors conclude that "environmental factors influence the records of the pullet year more than that of later years and influence flocks making low records more than those making high ones. Flocks of Leghorns with approximately the same yearly laying records will show the same distribution throughout the season regardless of whether the records were made in the first, second, or third year of production. Where a flock makes a low record the curve of distribution will be lower throughout than that of a high-laying flock, and, except for environmental fluctuations, the two curves will be practically parallel.

"Where the high and low layers of the same flock are compared, the low layers tend to fall off in production a little faster in the later part of the first season so that the first-year curves gradually separate toward the end. This was less noticeable in second-year production. High layers and low layers of the first and second years showed almost perfect agreement in distribution, with the curve of the low layers uniformly lower than that of the high layers or the difference slightly widening toward the ends. The distribution of production does not seem to be at all affected by age up to three years at least, but total production affects distribution regardless of age. . . .

"Winter egg production of flocks is more variable than annual production. This variation seems to be closely correlated with environmental factors. Flocks that made low winter records their first season made high ones the second, and vice versa. The flocks that made low records the first winter made higher three-year records than the high first-year flocks." The correlation between the first-winter production and that of later years averaged about This correlation is less for the high first-year flocks than for the low ones. The higher the production of an individual the greater the percentage of this production that will be made in the "winter" period regardless of age.

The correlation between winter production (November 1 to February 28) and total production of the same year, as shown by 18 flock records from 1907 to 1912, inclusive, averaged 0.5848. This correlation was found to decrease slightly with age, the averages for the six years being 0.6325 between the first winter and first year, 0.5862 between the second winter and second year, and 0.5351 between the third winter and third year.

"The winter period as used does not seem correctly to represent a biological entity, but is made up of the end of one period and the beginning of another. There does not appear to be any foundation for the assumption of a division of the laying period into units. It appears that there is a fairly definite 'productive rhythm' that not only affects annual production, but even influences the seasons so that a high fall production will be followed by a low spring one, and vice versa.

"The date of hatching when kept within a two-month period within the months of March, April, and May did not appear to affect total production in three years. The time between hatching and laying, while varying considerably under different environmental conditions, affected the total production in three years. The latest maturing pullets were always poorer producers."

Egg-production data from other sources are tabulated and discussed, from which it is noted that "the distribution of production of Leghorns in other flocks, including egg-laying contests, was found to agree with the corresponding curves from the Utah flocks. The distribution of production in the generalpurpose breeds was found to be quite different from that of the Leghorns. The curves of the general-purpose breeds reached their maximum early in the season and then rapidly fell off again to very moderate production, from which

they gradually declined to the end of the season, while the Leghorns reached their maximum a month or more later, but continued to produce heavily for several months and then rapidly fell off at the end."

Selection: The basis of improving the poultry flock, H. R. Lewis (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 12, pp. 4).—Brief directions are given for improving the egg production of flocks of hens by eliminating the poor producers, the basis of selection being the external appearance of the individual hens. It is stated that when culling a flock of yearling hens in the fall the following factors should be studied in the order named, and the final decision with regard to the possibilities of each bird made on the basis of a combined grouping of all the factors: Health, or freedom from disease; weight, or condition of flesh; vigor and stamina; condition of comb; pigmentation—amount of yellow in vent, ear lobes, beak, and shanks; condition of pelvic arch—size and pliability of lay bones, and distance between lay bones and from keel to pelvic bones; and condition of plumage—degree of molt, if any.

Feed cost of egg production. Results of three years' experiments at the Government poultry farm, H. M. Lamon and A. R. Lee (U. S. Dept. Agr. Bul. 561 (1917), pp. 42, pls. 8, figs. 5).—Owing to the lack of complete data on the feed cost of egg production on general farms, this experiment was undertaken at Beltsville, Md., in 1912 with 6 pens of 30 pullets, later increased to 16 pens. Only the feed costs are considered, as the fowls were mostly on free range. Some of the results of the work are as follows:

The average egg yield for the first-year pullets was 131, at a cost for feed of 10 cts. a dozen; the second year, 92.7, at a cost of 14 cts.; the third year, 78.2, at a cost of 19 cts. The average value of eggs over feed cost the first year was \$2.56 per hen, second year \$1.41, third year \$0.79.

Oats were not found necessary in the ration, but added variety. With the young fowls, especially, great gains were made with beef scrap or other animal protein. Cottonseed meal apparently produced brown or greenish spots on the yolks, rendering many of the eggs unfit for market. Fish meal at \$7 a ton less can replace beef scrap with no unfavorable effect on the quality of the eggs.

No advantage was found in allowing the fowls to select their own mash constituents over feeding the mixture.

In comparison of Leghorn and general-purpose fowls, it was noted that the Leghorns ate an average of 55 lbs. of feed annually at a cost of 87 cts., the general-purpose fowls 72 lbs. at a cost of \$1.13. The Leghorns produced eggs about 3 cts. per dozen cheaper during their first year than the general-purpose fowls, 6.4 cts. cheaper the second year, and 9.8 cts. cheaper the third year. The annual decrease in production was much less with the Leghorns than with the general-purpose breeds. The average weight per dozen of the eggs from the Leghorns during the first year was 1.45 lbs., second and third years 1.49 lbs.; from the general-purpose fowls, first year 1.53 lbs., second year 1.6 lbs., and third year 1.63 lbs.

Eggs were produced at the lowest cost in the spring and at the highest cost in the fall.

Poultry feeds and feeding results, R. N. Harvey (Texas Sta. Bul. 206 (1917), pp. 3-16, figs. 4).—Part one of this bulletin consists of a discussion of Texas-raised feeding stuffs suitable for poultry, and includes methods of feeding and some rations that have proved satisfactory.

Part two is a report of results of a feeding test carried on for five periods of four weeks each for the purpose of comparing meat scrap, cottonseed meal, meat scrap and cottonseed meal, and sour skim milk as supplements of milo maize, wheat bran, and wheat shorts for laying hens. The fowls receiving meat

scrap produced well during the first three periods, and those receiving skim milk did well throughout the whole 20 weeks. The flocks receiving cotton-seed meal and cottonseed meal with meat scrap gave very poor results, the former being very low twice, high once, but falling again. The latter was lowest one month, but was next to the lowest all other times. During the 20 weeks the hens fed cottonseed meal laid an average of 62.68 eggs and returned a profit of 77.98 cts. each over the cost of feed; those fed meat scrap laid an average of 67.86 eggs per hen, at a profit of 85.67 cts.; those fed meat scrap and cottonseed meal averaged 63.81 eggs each, at a profit of 72.8 cts.; and those fed sour skim milk an average of 71.29 eggs, at a profit of 87.54 cts. per hen.

Poultry farm management, R. E. Jones, I. G. Davis, and B. A. McDonald (Conn. Agr. Col. Ext. Serv. Bul. 8 (1917), pp. 16, figs. 4).—A study of the poultry business in Connecticut, based on the operation of 42 farms during one year. Receipts, expenditures, and inventories are noted, while labor income is taken as the measure of profit.

The average net receipts were \$1,312. Deducting interest on capital at 5 per cent, \$560, this gave a unit labor income of \$752.

The range of egg production was from 54 to 160, averaging 97 per hen for the year. Receipts from market eggs were 46 per cent of the total, and nearly four times as much as from any other single source. The necessity for increased average egg production is emphasized.

Forty-eight per cent of the expense on these farms was for feed. The home production of more feeds and the cooperative buying of others is suggested as means of lowering costs.

The greatest returns were made on the farms with the largest range. The importance of range and shade are noted.

The number of poultry units per man varied from 319 to 2,000. The highest efficiency lay between 800 and 1,500. With less than 500 a man can not make a profit, and with more than 1,500 he can not give them the necessary care for best results. The ratio of poultry units to laying hens was 100:68. The larger farms gave the higher percentages of profit, owing to greater efficiency of labor, machinery, and capital.

Finishing market poultry, W. C. Thompson (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 11, pp. 4).—Market requirements and the best means to market poultry at a profit when there is a tendency to become overstocked in certain classes are discussed.

### DAIRY FARMING-DAIRYING.

Dairy laboratory manual and notebook, compiled by E. L. Anthony (*Philadelphia and London: J. B. Lippincott Co., 1917, 2. ed., rev., pp. 72, figs. 15*).—A revised edition of these laboratory exercises (E. S. R., 31, p. 494).

Dairy cattle, A. Leitch, H. M. King, and J. P. Sackville (Ontario Dept. Agr. Bul. 253 (1917), pp. 72, figs. 23).—A general treatise on the economy of dairy farming, breeds of Ontario dairy cattle, principles of nutrition, use of feeds, general problems in dairying, care and management of dairy cattle, common diseases, and plans for the construction and equipment of dairy barns.

Experiments on the use of palm kernel nut cake as a food for dairy cows, A. LAUDER and T. W. FAGAN (Edinb. and East of Scot. Col. Agr. [Pamphlet], 1916, pp. 9).—Two experiments are here reported in which palm kernel nut cake and Bombay cottonseed cake were compared as feeds for dairy cows.

In the first experiment, which was conducted during the winter of 1915-16, two lots of nine Shorthorn dairy cows each were fed for eight weeks a daily

ration of 4 lbs. bran, 1 lb. locust bean meal, 75 lbs. turnips, and oat straw, supplemented by 4 lbs. palm nut cake for lot 1 and 4 lbs. cottonseed cake for lot 2. The weekly yield of milk before the experiment was 17.25 lbs. more for lot 2 than for lot 1. During the eight weeks of the experiment lot 1 produced 11,215.75 lbs. and lot 2, 10,962.75 lbs. of milk.

During the summer of 1916 two lots of eight cows each were fed for seven weeks on pasture supplemented with 4 lbs. cottonseed cake, 4 lbs. bran, and 1 lb. locust bean meal per day for lot 1, and 4 lbs. palm nut cake, 4 lbs. bran, and 1 lb. locust bean meal for lot 2. Previous to the experiment the milk yield of the two lots was practically equal. During the experiment the milk yield was 13,622.5 lbs. for lot 1 and 12,836.25 lbs for lot 2. The animals ate the palm kernel nut cake less readily than the cottonseed cake.

Analyses are given of the concentrates used in these experiments.

Calf feeding experiments (Dept. Agr. and Tech. Instr. Ireland Jour., 17 (1917), No. 2, pp. 257-259).—In a series of experiments at 30 centers in 17 counties crushed oats was compared with a standard calf meal composed of ground flaxseed, oat meal, and maize meal (1:2:2).

In the experiments, which lasted an average of 116 days, 202 calves were used. They averaged one-half week of age at the beginning of the test. The crushed oats ration was fed dry and the calf meal was steeped in hot water for 12 hours. An average daily gain of 1.41 lbs. per head was made on crushed oats and 1.44 lbs. on the calf meal. On the basis of prewar prices, the cost of production was 5s. 3d. per hundredweight (1.1 cts. per pound) less on crushed oats than on the calf meal.

The business of ten dairy farms in the blue grass region of Kentucky, J. H. Arnold (U. S. Dept. Agr. Bul. 548 (1917), pp. 12).—A brief analysis is given of 10 dairy farms found among the 187 farms previously noted (E. S. R., 36, p. 789).

The average labor income on these 10 dairy farms was \$1,773 and on the 187 farms \$750. The labor income on the seven successful farms of the ten varied from \$6,408 to \$1,121. The principal source of income on these farms was market milk, with cream next in importance, while very little butter was marketed. Receipts from the dairy represented 71 per cent of the total, the remainder consisting of tobacco (5.8 per cent), wheat, steers, poultry, and the sale of dairy cows, young stock, and calves. It is estimated that the cost of feed per cow on these farms varied from \$40 to \$50. The advantages of the bluegrass region for dairying are discussed.

A comparison of the seven more successful farms is made with the average of the whole group of ten. It is noted that "the average successful farm had the largest business, as shown by the size of farm, the number of dairy cows, and the working capital. On the average successful farm there were more receipts from crops and miscellaneous sources than were shown for the average of the ten farms. This indicates the greater degree of diversity on the successful farms. The most important comparison is that shown for the receipts per cow [\$164 and \$126, respectively]."

The effect of the ingestion of desiccated placenta on the variations in the composition of human milk during the first 11 days after parturition, F. S. Hammett and L. G. McNeile (Jour. Biol. Chem., 30 (1917), No. 1, pp. 145-153).—The results of this study demonstrate that the ingestion of desiccated placenta has an effect upon the factors concerned in the regulation of the chemical composition of milk. There is a stimulation of the sugar- and protein-producing mechanism with an apparent depression of the function of the fatsecreting apparatus.

From the peculiar characteristics of milk protein and carbohydrate it is presumable that these constituents are largely elaborated by the gland itself. Milk fat is apparently the sum total of the secretory and excretory activities of the mammary gland, the former being concerned with the elaboration of the fat peculiar to milk and the latter concerned in the inclusion in the milk of a part of the ingested fat as such. The evidence for this is admittedly incomplete. From the fact that the ingestion of desiccated placenta tends to produce a milk of greater uniformity in the change of production direction of fat, it does not seem improbable that its action may be stimulative to the secretory activity of the gland in this respect also.

A bibliography is included.

The modern milk problem in sanitation, economics, and agriculture, J. S. MACNUTT (New York: The Macmillan Co., 1917, pp. XI+258, pls. 16, figs. 22).—This book, which consists largely of a compilation of data from various sources, is a treatise on the practical, economic, and sanitary factors involved in supplying cities with pure milk.

Comparisons of the rate of gas production by certain bacteria in raw and in pasteurized milk, P. W. Allen (Jour. Infect. Diseases, 21 (1917), No. 2, pp. 219–225, figs. 3).—In this comparison of the physiologic activity of bacteria in milk all factors were the same with the exception that part of the milk was raw and part was pasteurized at  $60^{\circ}$  C.  $(140^{\circ}$  F.) for 30 minutes. It was found that pasteurization caused milk to become more favorable to the attack of the gas-forming colon bacilli and Bacillus arogenes. These results indicate that pure raw milk has a power of resisting changes which the same milk does not possess when pasteurized.

The significance of colon bacilli in milk, S. H. AYERS, L. B. COOK, and P. W. CLEMMER (Abs. Bact., 1 (1917), No. 1, pp. 52, 53).—In some experimental work in which a large number of samples of fresh milk produced under various conditions were examined, it was found that colon bacilli were present in 0.01 cc. in only a small percentage of the samples. When these organisms were found, their numbers ranged from 100 to 400 per cubic centimeter. There was apparently no increase in the colon count in milk held for 24 hours at 10° C. (50° F.) but a very great increase at 15.5° C. (60° F.).

In order to determine how many colon bacilli could be introduced into fresh milk, an examination was made of 70 samples produced under extremely filthy conditions and handled in unsterilized utensils. These conditions were far worse than would probably be found on any farm, yet in only 32 of the 70 samples were colon bacilli found in 0.01 cc. of fresh milk. The number of these organisms found in the 32 samples ranged from 100 to 28,400 per cubic centimeter, but only one sample showed more than 2.000. Leaving out this sample, the average colon count of the 31 samples was 648 per cubic centimeter.

The influence of gargety and high count cows on the number of bacteria in milk, R. C. Colwell (Abs. Bact., 1 (1917), No. 1, pp. 48, 49).—The investigation of a sanitary dairy of 140 cows from which raw milk was retailed in the city of Providence, R. I., showed two factors to be responsible for the production of milk with more than 10,000 bacteria per cubic centimeter, (1) high count cows, cows whose freshly and aseptically drawn milk contains more than 10,000 bacteria per cubic centimeter, and (2) gargety cows, cows affected with incipient, acute, or chronic mammitis. The results of 243 tests of individual cows showed that 72 per cent of the cows were producing milk containing less than 10,000 bacteria per cubic centimeter, and 28 per cent were cows of the high count type.

A certain few of these high count cows were infected with mammitis in one quarter of the udder and a bacteriological examination of each teat of such

cows was made. In every instance where by physical examination one quarter was known to be infected one or more of the apparently healthy quarters proved to be infested with similar organisms. The custom of discarding only the milk from the infected quarter and of adding the milk from the remaining quarters to the whole milk of the herd was therefore responsible for infecting the entire output with the gargety milk.

Dairy laws of Wisconsin (Madison, Wis.: Dairy and Food Comr., 1917, pp. 40).—The text is given of the dairy laws of Wisconsin and of rules and regulations effective July 1, 1917, governing the licensing of butter makers and cheese makers and operators of butter and cheese factories, adopted by the dairy and food commissioner under authority of law.

Testing milk for butter fat by the Babcock test, compiled by W. E. EVANS (Neffsville, Pa.: Author, 1917, pp. 16, figs. 13).—Brief directions are given for making the Babcock fat test on whole milk, together with notes on the causes of variation in the fat content of milk.

Accounting records for country creameries, J. R. Humphrey and G. A. Nahstoll (U. S. Dept. Agr. Bul. 559 (1917), pp. 37).—This bulletin contains copies of forms and a description of their uses for a system of accounts which is being recommended by the Bureau of Markets and by the Dairy Division of this Department as a uniform system of accounting for country creameries. It is stated that the system presented is the result of careful study and practical experience in creameries operating under widely varying conditions.

Experiments with pepsin to replace rennet, D. W. Steuart (Jour. Bd. Agr. [London], 24 (1917), No. 1, pp. 57-59).—The author made up a pepsin solution that compared favorably with standard rennet extract and kept well. Caerphilly, Smallholder, and soft cheeses made by the use of the pepsin solution compared favorably with rennet cheese. In making a gallon of the pepsin solution, he advises the use of 13\frac{1}{3} oz. of \(\frac{1}{2}.\dot{1}\dot{1}\dot{2}\dot{1}\dot{2}\dot{2}\dot{2}\dot{2}\dot{1}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{1}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{2}\dot{

Loss of fat in the whey when using pepsin, G. H. BARR (Agr. Gaz. Canada, 4 (1917), No. 8, pp. 660-662).—Tabulated results are given of cheese making experiments at the Finch Dairy Station from February 23 to May 10, 1917.

In using pepsin, the best results were secured by setting at a temperature of 85° F. and using enough pepsin to coagulate the milk ready to cut in from 25 to 30 minutes. Setting the milk at temperatures over 86° increased the loss of fat in the whey in nearly every case. The loss of fat in the whey was lessened by increasing the quantity of pepsin per 1,000 lbs. of milk from 4 oz. to 5.5 and 6 oz. Developing the acidity in the milk so that the curds dipped in less than 2 hours and 15 minutes from time of setting increased the loss of fat in the whey to a marked extent. It was found advisable to allow the curd to get fairly firm but not too firm before cutting.

Varying conditions in the milk from day to day as found in cheese factory work apparently affect the loss of fat in the whey to a greater extent when pepsin is used than when rennet extract is used. Care must therefore be exercised in cutting and stirring the curd when making cheese with pepsin.

On the formation of "eyes" in Emmental cheese, W. M. CLARK (Jour. Dairy Sci., 1 (1917), No. 2, pp. 91-113, figs. 2).—A review of the literature reveals little or no evidence that the eyes of Emmental cheese are strictly localized at points of excessive bacterial growth. On the contrary the evidence of bacterial counts and direct microscopical examination, as well as the gas production of different regions of the cheese, indicate a more or less uniform distribution of the eye distending gas.

Certain theoretical considerations are presented which lead to the hypothesis that the gas separates in aggregates according to laws governing the separation of gas from supersaturated aqueous solutions. This hypothesis has been tested upon viscous media with results directly applicable to the "eye" and "Nissler" hole formations in cheese.

It is concluded that the gas produced in Emmental cheese separates in aggregates whose localities have no necessary relation to the points where the gas is produced, and that a rapid gas production must tend to the formation of numerous small holes while a slow gas production must admit the formation of larger holes. This conclusion is shown to agree with the fact that Nissler holes are produced by a rapid fermentation while eyes are formed slowly. This conclusion also suggests that the gas of Nissler holes must separate at numerous points near its point of origin without regard to any particular locality of the cheese, while the eyes must form at favorable points. This was experimentally verified by a study of stained cheeses.

An extensive bibliography is given.

#### VETERINARY MEDICINE.

[Live stock diseases] (In Live Stock of the Farm, edited by C. B. Jones, London: The Gresham Publishing Co., 1915, vol. 4, pp. 159-252, figs. 18; 1916, vol. 5, pp. 101-134, 249-269).—The diseases of sheep are dealt with by T. W. Cave in volume 4 (pp. 159-252); and the diseases of pigs (pp. 101-134) and of poultry (pp. 249-269) by H. Leeney in volume 5.

New and nonofficial remedies, 1916 (Chicago: Amer. Med. Assoc., 1916, pp. 428+XXII).—Descriptions are given of the articles which had been accepted by the council on pharmacy and chemistry of the American Medical Association prior to January 1, 1916.

Sugar in the treatment of wounds, S. Koheya (Chosen Igaku Kai Zassi, No. 13 (1916), pp. 11-18; abs. in Japan. Med. Lit. [Korea], 2 (1917), No. 1, pp. 7, 8).—The successful use in wound treatment of commercial granulated sugar is noted. The sugar was found to inhibit the growth of most of the bacteria liable to be found in wounds. It possessed no disinfecting power, but stimulated tissue granulation and the formation of epithelial cells, prevented putrefaction of the secretions, and reduced the odor.

The use of chloramin-T paste for the sterilization of wounds, M. Dau-FRESNE (Jour. Expt. Med., 26 (1917), No. 1, pp. 91-93).—"Dakin's toluene sodium p-sulphochloramid, mixed with sodium stearate, forms a paste sufficiently active and stable to be used in the treatment of wounds."

Sterilization of wounds with chloramin-T, A. CARREL and ALICE HARTMANN (Jour. Expt. Med., 26 (1917), No. 1, pp. 95-118, figs. 20).—"Under the conditions of our experiments chloramin paste maintains the asepsis of a wound already sterile, and sterilizes an infected wound. Under the same conditions chloramin paste causes no apparent modification of the cicatrization curve of an aseptic wound."

Dichloramin-T in the treatment of the wounds of war, J. E. SWEET (Jour. Amer. Med. Assoc., 69 (1917), No. 18, pp. 1076-1078; Brit. Med. Jour., No. 2956 (1917), pp. 249, 250).—The author concludes that Dakin's dichloramin-T in solution in eucalyptol and paraffin oil is of great advantage in wound treatment, even when the final results in wound healing are no better, because it saves the pain of wound dressing, it effects an appreciable saving of dressing material, the amount of solution is of small bulk, the number of wounds which a surgeon can dress in a given time is far greater than by any other method.

and the elimination of the Carrel tube simplifies the dressing, the problem of transportation of the wounded, and the time taken for the periodic flushing.

The relation between the thromboplastic action of cephalin and its degree of unsaturation, J. McLean (Amer. Jour. Physiol., 43 (1917), No. 4, pp. 586-596).—Experiments with various samples of cephalin have shown that its thromboplastic action bears a direct relation to its degree of unsaturation. The greater the degree of unsaturation the greater the thromboplastic activity. Cephalin saturated beyond a certain degree, either by reduction or oxidation, loses completely its thromboplastic activity. The material in solution which has become saturated or partly saturated yields an acid reaction and retards the coagulation of blood. With increasing saturation the material gradually loses its property of solution in ether and chloroform.

It is noted that cephalin is most effective in its coagulative power shortly after its isolation from the tissues.

The reaction of sera as a factor in the successful concentration of antitoxic sera by the methods at present in use, Annie Homer (Biochem. Jour., 11 (1917), No. 1, pp. 21–39, figs. 2).—The results of the study reported show that in the Banzhaf¹ method for concentration of antitoxic sera the uncertainties of filtration are due to no account having been taken of the reaction of the serum, and that, as the precipitating power of 30 per cent ammonium sulphate is not appreciably increased during the heating, a certain amount of euglobulin escapes precipitation with the first fraction precipitate and appears in colloidal suspension in the final product. "The uncertainties in the filtration of the hot serum-ammonium-sulphate mixtures in the above method can be obviated by an adjustment of the hydrogen ion concentration. The filtration can also be improved by the addition of sodium chlorid to the mixtures, but in this case the improvement is due to a specific action of salt on the globulins."

Euglobulin can be completely eliminated by adjustment of the hydrogen ion concentration of the serum mixtures to the point at which the desired increased precipitation is assured, by brine extraction of the second fraction precipitate containing the pseudoglobulin-antitoxin combination, subjecting the serum to a preliminary prolonged heating at from 57 to 58° C., and the addition of organic substances such as phenol and its homologues, ether, or chloroform. "The extent of the heat denaturation of the serum proteins during the heating of serum at 57° for several hours is also influenced by the hydrogen ion concentration of the serum and can be controlled by the adjustment of the latter. The denaturation induced by heat in alkaline sera apparently does not involve the same type of change as that induced in acid sera."

Equilibria in precipitin reactions.—The coexistence of a single free antigen and its antibody in the same serum, S. BAYNE-JONES (Jour. Expt. Med., 25 (1917), No. 6, pp. 837-853, fig. 1).—In the study reported the purified proteins, edestin from hempseed and crystalline ovalbumin from fresh eggs, were used as antigens. Although the albumin isolated was considered as pure as is obtainable by chemical means, moderately severe anaphylactic reactions were produced by it in animals sensitized with ovoglobulin. It is noted that "anaphylactic tests of the individuality of a protein can not be any longer regarded as the criterion of the purity of the substance as an antigen. . . .

"With edestin and crystalline egg albumin as antigens, phases in the precipitin reaction were found in which these substances and their specific precipitins could be demonstrated to be coexistent but ununited in the same serum. When edestin or crystalline egg albumin is injected into a rabbit immunized thereto, the antigen may be found in the circulating blood during 48 hours after

<sup>&</sup>lt;sup>3</sup> Collected Studies Research Lab. Dept. Health N. Y. City, 4 (1908-9), pp. 230-232.

its injection, while at the same time the animal maintains a high titer of free precipitin in its blood. When the pure protein antigen is mixed in proper proportions with the serum of a specifically immunized rabbit and the resulting precipitate removed by centrifugation, the supernatant fluid contains both antigen and antibody. The serum drawn from a rabbit during the period in which free antigen and antibody are coexistent in the circulation undergoes slow spontaneous precipitation when kept in sterile tubes in the ice box." The interaction appears to take place according to a definite law.

The protective action of a solution of egg albumin as a third colloid inhibiting precipitation in a reaction between human serum and its antibody was demonstrated.

Notes on the outbreak of foot-and-mouth disease at Butleigh, Somerset, R. N. Grenville (Jour. Bath and West and South. Counties Soc., 5. ser., 11 (1916-17), pp. 82-84).—Evidence is presented which indicates that the infection was carried to cows at Butleigh by a cart, probably in the mud on its wheels.

The value of the ophthalmic and conglutination tests in the diagnosis of glanders, E. Gräub (Schweiz. Arch. Tierheilk., 59 (1917), No. 3, pp. 129-154).— In the examination of a large number of remounts the ophthalmic reaction was found to yield fairly satisfactory results, although some doubtful reactions were obtained. The conglutination test was the most reliable, no doubtful reactions having been observed in the examination of 3,000 sera.

The ophthalmic reaction and a simplified conglutination reaction are described in detail. In the simplified technique, horse serum is used instead of guineapig serum to furnish complement.

The temperature required for the "inactivation" of mule blood for the complement fixation test for glanders, J. B. Buxton (Vet. Jour., 73 (1917), No. 505, pp. 245-247).—In the examination of blood samples from a large number of mules by the complement fixation method it was found that an unusually large number of animals gave a definite positive or an indefinite reaction. Postmortem examination of certain animals which had given a positive reaction to the complement fixation test failed to show the presence of glanders lesions. The indefinite reaction was found to be due to insufficient inactivation of the mule serum and a consequent destruction of anticomplementary bodies. Experimental data submitted show that heating of the serum to 62° C. for one-half hour is necessary for complete destruction of these anticomplementary bodies.

Transmission of pulmonary and septicemic plague among marmots, Wu Lien-Teh and F. Eberson (Jour. Hyg. [Cambridge], 16 (1917), No. 1, pp. 1-11).—Of marmots placed in contact with marmots infected with plague by inhalation, "52.6 per cent developed pulmonary plague and died within four to six days. Marmots suffering from pneumonic plague are infective at an early stage of the disease and the animals which such marmots infect acquire plague after a short incubative period.

"Pulmonary plague can be readily transmitted to the small marmot (Spermophilus citellus), and these animals, when suffering from pulmonary plague, are in turn capable of transmitting the same type of plague through the respiratory passages. Septicemic plague can be developed in marmots very easily as a result of respiratory infection, and also by direct subcutaneous inoculation with small amounts of culture. The marmot can acquire plague by way of the alimentary tract and spread the disease by feeding on plague-infected carcasses. The histological appearances observed in the lesions of these cases are characteristic."

In an appended note G. H. F. Nuttall reports upon the identification of ectoparasites collected from marmots by the senior author. These included a flea determined by Rothschild as a slightly aberrant specimen of *Ceratophyllus famulus* and a number of ticks closely resembling Hamaphysalis koningsbergeri.

Note on the transmission of animal trypanosomiasis in northern Rhodesia by bloodsucking flies other than Glossina, F. Chambers (Vet. Rev., 1 (1917), No. 3, pp. 222-227).—"From the evidence obtained it would appear that the trypanosome can be and is spread in tsetse-free areas by the agency of biting flies. That Tabanidæ are the worst offenders is becoming realized. Pangonia and Stomoxys have also been shown to be transmitting agents, and it is possible that any bloodsucking fly can transmit trypanosomiasis mechanically."

Tuberculosis and animal breeding, U. Duerst (Schweiz. Arch. Tierheilk., 59 (1917), Nos. 2, pp. 65-91, figs. 2; 3, pp. 154-173, fig. 1).—This is a general discussion of the subject, together with some original experimental data.

The author shows that the statistical data in regard to the frequency of tuberculosis in man as well as in animals, reported by districts, or findings in abattoirs do not, in general, give a correct indication of the spread of the disease among animals. The classification by age should be taken into account. As has been earlier suggested, the frequency of tuberculosis increases with age, but only to a definite point. This establishes an average curve of the frequency of the disease, and by its use the frequency can be calculated in any locality if the age classification of the animals in the particular locality is known.

In regard to the spread of the disease, the dust in the stable plays an important part, as well as the general condition of the stable. The larger the stable and the more animals together, the greater is the percentage of infections. It is indicated that more attention should be paid to construction of buildings for the animals. Small compartments, rather than the housing of many animals in one large compartment, are recommended.

The degree of susceptibility is considered to depend on the general state of the constitution of the animal. Experimental data show that excessive inbreeding weakens the constitution. Acclimatization and too frequent pregnacies are also considered to weaken the constitution and to be predisposing factors to the disease.

A bibliography of 81 references to the literature cited is appended.

Presence of tubercle bacilli in the feces of cattle in dairy herds, R. S. WILLIAMS, W. M. SCOTT, T. ROBERTS, and W. A. HOY (Vet. News, 14 (1917), Nos. 695, pp. 171-173; 696, pp. 180-184, figs. 2).—Samples of feces from 179 cows were examined for tubercle bacilli. Eliminating the cases which did not react to the tuberculin test and the tests which failed, virulent tubercle bacilli were found in the feces of 3 of the remaining 158 animals.

The experimental technique used is described and the results of the investigation discussed.

The incidence of bovine infection of tuberculosis in man, Chung Yik Wang (Jour. Path. and Bact., 21 (1917), No. 2, pp. 131-172).—The author divides the cases of tuberculosis examined by him into the following groups: Cases which showed definite active lesions of tuberculosis in the body on microscopic examination; cases which, while showing no evidence of a definite active tuberculous infection in any part of the body, revealed certain lesions apparently of a tuberculous nature in the form of caseous glands or calcareous deposits in the glands or the lungs; cases in which either no change or only a simple increase in size or softening of one or more glands, unassociated with any evidence of

tuberculosis, could be demonstrated; and cases in which the sputum alone was examined.

The cases coming under the third group have been previously reported, as well as those under the fourth group (E. S. R., 37, p. 180).

The 123 strains of tuberculosis bacilli obtained from 88 cases under groups 1 and 2 were investigated bacteriologically and found to conform to either human or bovine types of the bacillus. No atypical strain was demonstrated. When two or more strains were isolated from a single case their cultural characteristics were identified. Out of 68 cases of adults, bovine tubercle bacilli were separated in 7 instances, 1 from 29 sputum cases, 2 from 4 cases of abdominal tuberculosis, 2 from 7 cases of generalized tuberculosis, and 2 from 28 cases in which the only signs of the disease were the calcareous or caseous lesions. Three of the bovine cases gave indication on post-mortem examination that the path of infection was by way of the intestine. In three others the evidence of primary infection was inconclusive, while in the remaining case (sputum case) no post-mortem was performed.

The bacteriological examination of 20 cases in children resulted in the isolation of the bovine type in 11 instances. In 9 of these cases the primary site of infection was found to be in the intestine. In the remaining 2 instances the evidence was inconclusive.

The protocols of the cases of groups 1 and 2 are submitted, together with the bacteriological data, in detailed tabular form.

A bibliography of 26 references to the literature is appended.

Tuberculosis in carnivorous animals, W. R. Blair (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 6, pp. 750-767).—This is a general discussion of the prevalence, symptoms, and lesions of the disease, together with a number of case reports of dogs, cats, and other carnivorous animals in captivity.

The author's experience in the use of tuberculin as a diagnostic agent in dogs has been unsatisfactory. Its use on cats is indicated as being uncertain, and dangerous for animals free from the disease.

Tuberculosis in the horse, F. Chambers (Vet. Jour., 73 (1917), No. 505, pp. 242, 243).—The author reports four cases of tuberculosis in the horse, the diagnosis of which was made on post-mortem examination. Autopsical data are included.

During the life of the animals tuberculosis was not suspected in any of these cases. It is thus indicated that all cases of general debility which show no improvement in a few weeks should be tested for tuberculosis.

Antituberculosis vaccination, RAPPIN (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 10, pp. 421, 422).—The preparation of a vaccine which yielded good results is described as follows:

Tubercle bacilli obtained from bouillon cultures of different ages and desiccated for 24 hours are treated with a 2 or 3 per cent solution of sodium fluorid for several days. By this treatment the organisms lose their infective powers but retain their toxic properties. The bacilli are washed with physiological salt solution and then submitted for a longer or shorter period to the action of an antituberculosis serum. This emulsion of the bacilli in the serum constitutes the vaccine.

Effect of tethelin on experimental tuberculosis, H. J. Corper (Jour. Infect. Diseases, 21 (1917), No. 3, pp. 269-278).—The subcutaneous injection of 25-mg. doses of tethelin, isolated by Robertson (E. S. R., 35, p. 8), on alternate days for 18 days into guinea pigs infected with virulent human tubercle bacilli had no appreciable effect on the progress of the disease or the duration of life of

<sup>&</sup>lt;sup>1</sup> Lancet [London], 1916, II, No. 10, pp. 417-419.

the experimental animals. The daily subcutaneous administration of 25-mg. doses of tethelin to guinea pigs sensitized by dead and living human tubercle bacilli had no appreciable effect on the development, recession, or rupture of intracutaneous tubercles produced by dead human tubercle bacilli nor on deep puncture wounds of the skin in the animals used.

Observations on the presence of the Bacillus abortus bovinus in certified milk, E. C. Fleischner and K. F. Meyer (Amer. Jour. Diseases Children, 14 (1917), No. 3, pp. 157-173).—This is a report of preliminary studies at San Francisco, Cal., accompanied by a list of references to the literature.

The authors conclude from the examination of a limited amount of material that "B. abortus is, for practical purposes, always present in the certified milk produced in the San Francisco Bay regions. Tubercle bacilli are not present in this same milk in sufficient number to give tuberculosis to guinea pigs, although this conclusion may prove incorrect on further experimentation. If the above conclusion is correct, there is no necessity for pasteurizing certified milk on account of any danger that it may possess as a disseminator of bovine tuberculosis to infants.

"It is not unlikely that, in many previous milk tests for tubercle bacilli, the anatomic lesions of bovine abortion disease in the guinea pig were mistaken for tuberculosis. If the *B. abortus* is present in certified milk to the extent evident from these experiments, it is difficult to consider it pathogenic for infants, without, so far as is known, ever having produced recognizable lesions on post-mortem examination. The result of this work, however, is one more definite indication that it is of greatest importance to study the abortus problem from every angle to be absolutely certain of its bearing on the health of infants."

Tick eradication laws and regulations of the State of Arkansas, R. M. Gow (Arkansas Sta. Bul. 132 (1917), pp. 8).—The text of the State tick eradication laws and regulations is given, with notes.

A note on the immunity of suckling pigs to hog cholera, R. R. Birch (Cornell Vet., 7 (1917), No. 3, pp. 199, 200)—The author notes an instance in which two pigs of a hyperimmune sow died from natural exposure to hog cholera at the ages of 31 and 37 days, respectively. Another pig from the same litter died at the age of 27 days, but there was some doubt as to the definite cause of death in this animal. The pigs were all nursed by a hyperimmune mother until they refused food on account of sickness.

It is indicated that "these observations add emphasis to the fact that, although pigs of immune sows are often immune while being sucked, it is not always safe to depend on this immunity."

A serum test influenced by Ascaris infestation, R. R. Birch (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 5, pp. 694-696).—The author, who has frequently observed that when exposed to hog cholera pigs infested with ascarids die much more quickly than normal ones, especially if the parasites have entered the gall duct, has found that ascarids are responsible for the differences obtained from serum and virus. He thinks it quite probable that disastrous results would follow simultaneous treatment of pigs badly infested if light doses of serum were administered.

Experiments in filtration of antihog-cholera serum, B. H. EDGINGTON, A. BROERMAN, and E. W. PORTER (*Jour. Infect. Diseases, 21 (1917), No. 3, pp. 258–264*).—In the study reported attempts were made to produce bacteria-free antihog-cholera serum by passage through Berkefeld and Chamberland F filters.

The results obtained indicate that the immune bodies of antihog-cholera serum are restrained by filtration through Chamberland F filters. The Berke-

feld filter was found to restrain the immune bodies of the serum as well as the Chamberland filter. "When Berkefeld filtrate was in turn passed through a Chamberland F filter, the resulting residuum was not sufficiently potent in a dose of 20 cc. to protect the test animal against simultaneous inoculation with 2 cc. of hog-cholera virus."

A potent bacteria-free antihog-cholera serum could not be obtained by filtration through either Berkefeld or Chamberland F candles. It is indicated that absorption of the proteins in the blood serum always takes place in the filter pores, so that finally the filtration is actually through a colloid filter. With such a condition, the first portion of the filtrate passing through the candles may have contained immune bodies, while the latter portion may have been free of these products.

The possibility of the production of a potent bacteria-free antihog-cholera serum by filtration of serum obtained through normal clotting or by centrifugalizing defibrinated blood is noted. No experiments to determine this, however, were carried out.

Hog cholera control, R. A. CRAIG and L. C. KIGIN (*Indiana Sta. Circ. 62* (1917), pp. 8, figs. 9).—A popular summary of information on hog cholera and measures for its control.

The statistics for Indiana show that the death rate in hogs in that State varies from 6.2 to 24.7 per cent per year. The average for a period of six years (1910–1915) was about 13 per cent.

Sanitary measures to prevent hog cholera, R. Graham (Illinois Sta. Circ. 203 (1917), pp. 3-8).—A popular summary of information.

Crude oil for hogs, J. M. Evvard (Iowa Agr., 18 (1917), No. 5, pp. 207, 208).— The author recommends the use of crude oil for the destruction of lice and nits on hogs, applied by sprinkling over them.

#### RURAL ENGINEERING.

Construction and use of farm weirs, V. M. Cone (U. S. Dept. Agr., Farmers' Bul. 818 (1917), pp. 18, figs. 5).—This is based on work done under a cooperative agreement between the Office of Experiment Stations of the U. S. Department of Agriculture and the Colorado Experiment Station. Its purpose is to give practical directions for the construction and use of the smaller sizes of weirs, such as are suited to the measurement of water on irrigated farms. A technical report on the experimental data involved has been previously noted (E. S. R., 34, p. 881).

A new evaporation formula developed, R. E. Horton (Engin. News-Rec., 78 (1917), No. 4, pp. 196-199, fig. 1).—An empirical statement based on physical laws is given which was found to agree with observed facts and is held to be an improvement over existing formulas. The working formula is E=C [ $\Psi$  V- $\nu$ ] in which E=evaporation, C=a constant, V=vapor pressure corresponding to liquid surface temperature, and  $\nu=$ atmospheric vapor pressure. A diagram is given showing values of  $\Psi$ , the wind factor variation for different wind velocities.

Investigations along the central and lower Volga region.—I, Irrigation in the Novouzensk district.—Basin of the Greater Utzen, N. S. Frolov (Trudy Organizatsii po Izyskaniam i Rabotam v Srednem i Nizhnem Povolzh'æ. vol. 3, pt. 1, sect. 1, Oroshenie v Novouzenskom Uæzdæ. Saratov: Min. Zeml., 1915, pp. IV+250, pls. 16).—This volume covers the history and economics of irrigation in the Novouzensk district and gives the program and extent of irrigation investigations, special attention being given to so-called silt irrigation.

Irrigation experiments in rice culture, P. VAN DER ELST (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Rijst., No. 2 (1916), pp. 52, pl. 1, figs. 6).—This is a description of the methods and purpose of irrigation water measurement and distribution experiments and of drainage of irrigated land experiments with special reference to rice lands.

Irrigation experiments in rice culture, P. van der Elst (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Rijst., No. 3 (1916), pp. 71, pls. 4).—The details of irrigation and drainage experiments on rice soils in several districts of Java are described. These included especially work on the measurement and distribution of irrigation water.

Organization, financing, and administration of drainage districts, H. S. Yohe (U. S. Dept. Agr., Farmers' Bul. 815 (1917), pp. 37).—This publication is intended to aid landowners, district officials, and others interested in forming drainage districts for the purpose of reclaiming swamp and overflowed lands. "It presents methods of organizing the interested property owners and principles which should be considered in the administration and financing of drainage districts. It is particularly applicable to drainage districts in the humid regions of the United States."

"Before promoting a drainage district consideration should be given to the economic conditions prevailing in the section in question, the agricultural value of the soil, and the demand for more agricultural land on the part of resident landowners. The cost of draining the land as compared with the market prices of other lands possessing equal agricultural value and not needing drainage should be learned. The sentiment of the property owners toward drainage should be ascertained. The success of the project requires the cooperation of more than a bare majority. Unless funds sufficient to construct adequate improvements can be obtained, the undertaking of the project generally would not be warranted. . . .

"Since drainage districts come into being only through the law, it is highly essential that the law be complied with in every detail. The need of retaining a competent attorney is apparent at the very beginning.

"The three principal reasons for forming a drainage district of wet lands which it is desired to reclaim are (1) to provide a method of equitably distributing costs among the landowners and a means of collecting such taxes, (2) to issue bonds to finance the district, (3) to obtain authority to condemn whatever land may be needed for the general use of the district. Each of these factors is vitally important to the promotion of the project....

"The drainage commissioners must insist on employing the best talent they can afford to design and construct the improvements. So-called cheap engineering and construction must be guarded against. Bids for construction which on their face appear a great deal less than others should be scrutinized closely. . . . The importance of employing reputable consulting engineers to pass upon the plans before their final approval and adoption should not be overlooked. In selecting officials to administer districts the landowners should be guided by the same principles that govern the selection of directors for successful commercial and industrial enterprises. . . . In appointing engineers, attorneys, and other assistants, in awarding contracts, and in selling bonds the commissioners should so govern themselves as to win the confidence of the landowners."

Report of the water laboratory, H. E. BARNARD (Ind. Bd. Health, Ann. Rpt. Chem. Div. Lab. Hyg., 10 (1915), pp. 87-94, figs. 4).—Of 1,520 samples of water from private and public sources in Indiana analyzed during 1915, 63.5 per cent were classed as good, 30.8 per cent as bad, and 5.7 per cent as doubtful. Of

the total number examined 1,295 were from private supplies, of which 570 came from deep wells, 555 from shallow wells, 37 from cisterns, and 63 from springs; 785 of the private supplies were potable, 437 were bad, and 73 doubtful.

Of the total number of 690 deep well supplies examined 552 were classed as good, 103 as bad, and 35 of doubtful quality. Of the 569 shallow well samples analyzed but 243 were good, 291 were bad, and 35 were of doubtful quality. Of the 84 springs analyzed 56 were found to be good, 21 bad, and 7 were of doubtful quality. Of the 37 cistern waters examined but 14 were good, 18 were listed as bad, and 5 were of doubtful quality. Nineteen of the 23 pond and lake supplies examined were good and 4 were bad.

Sterilization of water in the field, H. Penau (Jour. Pharm. et Chim., 7. ser., 13 (1916), No. 12, pp. 377-385; abs. in Chem. Abs., 10 (1916), No. 19, p. 2487).— A process is described in which a solution of sodium hypochlorite containing 10 gm. of active chlorin per liter is prepared by double decomposition of calcium hypochlorite with sodium carbonate and potassium permanganate and is added at the rate of 0.5 liter per 1,000 liters of water. After 45 minutes 60 cc. of an aqueous 10 per cent solution of sodium thiosulphate is added. It is found that colon bacilli are destroyed while the odor and taste of the water are not impaired.

Sewage disposal for school buildings in Ohio, R. S. Durrell and D. E. Adams (Ohio Pub. Health Jour., 7 (1916), No. 8, pp. 326-338, pls. 6).—"The purpose of this bulletin is to acquaint boards of education, and their architects and engineers, in the general methods of sewage disposal for school buildings not accessible to sanitary sewers, and in the design of the separate features involved. It is not intended to provide standard working drawings for the construction of sewage-treatment plants for these buildings. The accompanying plates illustrate not only the essential details but also the principal features to be observed in preparing plans for submission. These plans illustrate sewage-treatment plants which are applicable for schoolhouse locations under typical Ohio conditions."

The operation of sewage treatment plants for public buildings, D. E. Adams (Ohio Pub. Health Jour.. 8 (1917), No. 1, pp. 20-30, figs. 2).—Instructions as to the proper operation and maintenance of sewage-treatment plants for public and private institutions and schools are given.

The expansion and contraction of concrete and concrete roads, A. T. Goldbeck and F. H. Jackson, Jr. (U. S. Dept. Agr. Bul. 532 (1917), pp. 31, pls. 3, figs. 16).—Laboratory and field tests begun in 1910 on expansion and contraction movements by concrete pavements are reported. These included detailed attention to the spacing, design, and movement of expansion joints.

It was found that neat cement, when allowed to dry, first contracted rapidly, then more slowly. The amount of contraction seemed to vary with the cement, size of specimen, and condition of atmosphere in which drying took place. The amount at 28 days was about 0.1 per cent and at six months about 0.2 per cent.

Mortar contracted on hardening in air and expanded on hardening in water. The contraction in warm, dry air at 28 days was about 0.045 per cent for 1:2 and 1:3 mortar and at six months was 0.078 for 1:3 mortar and 0.085 for 1:2 mortar. The expansion in water was 0.01 per cent for 1:3 and 0.017 for 1:2 mortar at 28 days, and at six months 0.013 for 1:3 and 0.02 per cent for 1:2 mortar.

Both 1:2:4 and 1:3:6 concrete contracted on drying in warm, dry air from 0.02 to 0.04 per cent at 28 days and from 0.04 to 0.07 per cent at six months. When hardening in water an expansion of about 0.01 per cent took place at 28 days and at six months in 1:2:4 and 1:3:6 concrete. The richness of the

mix of concrete seemed to exert a small influence on the contraction; the richer the mix the greater was the change in length.

Concrete alternately wetted and dried was made to expand and contract owing to these causes. The expansion due to wetting was more rapid than the contraction on drying. The thoroughly dried specimens of concrete did not recover their original wet length when immersed. Concrete stored in the outer air and exposed to the weather did not contract to the same extent as the above-described specimens, except under very dry conditions. A waterproof covering, such as coal tar, prevented the rapid change in moisture content and greatly retarded the expansion and contraction. Reinforcement decreased but did not prevent the shrinkage and expansion of concrete due to drying, and had no effect on temperature changes.

"Reinforcement can not therefore entirely prevent cracks, but seems to distribute them and keep them small. Concrete roads are affected by both temperature and moisture. When the drainage is good and the sub-base not wet, the temperature effects seem to be most important. A wet sub-base may add to the temperature expansion by about 0.01 to 0.02 per cent. The restraining effect of friction at the base seems to be almost negligible when figuring temperature and moisture expansion and contraction. In very dry climates shrinkage due to drying must be added to contraction due to fall in temperature. A shrinkage of 0.04 per cent (0.25 in. in 50 ft.) is a safe allowance due to drying.

"Temperature at time of construction of road should be considered in designing joints. Cold-weather construction requires a full allowance for temperature expansion, and on wet sub-bases for moisture expansion also. Hot-weather construction theoretically requires no joints at all, even in wet sub-bases, as the temperature contraction exceeds the moisture expansion. However, the difficulty of keeping the cracks clear probably renders joints imperative."

Toughness of bituminous aggregates, C. S. Reeve and R. H. Lewis (U. S. Dept. Agr., Jour. Agr. Research, 10 (1917), No. 7, pp. 319-330, pls. 2).—Tests of the toughness of several representative samples of various types of rock when used as aggregates in bituminous mixtures are reported, it being concluded that the toughness of bituminous aggregates in which a given bituminous material is tested will not be the same for every type of rock.

"Tests of laboratory specimens can be directly correlated with results in service. The difference in behavior of the various rock types can not be directly attributed to any of the routine physical test values of the rock, but appears to be due largely to differences in the surface character of the rock particles. While relatively soft or fluid bitumens may yield satisfactory results in bituminous concrete with some types of rock, their use with other types will lead to failure of the road surface. The impact or toughness test of bituminous aggregates offers possibilities as a means of determining in advance the relative behavior in service of bituminous concretes. While the authors at this time have no definite recommendations to offer with regard to their last conclusion, it may be stated that further experiments will be made with that end in view."

Concrete culverts (Cement and Engin. News, 29 (1917), No. 4, pp. 109, 110, flgs. 4).—Comparative cost data on cast-iron and reinforced concrete culvert pipe for road use are given, showing in general the economy of the latter type of construction.

Mechanical properties of woods grown in the United States, J. A. Newlin and T. R. C. Wilson (U. S. Dept. Agr. Bul. 556 (1917), pp. 47, pls. 3).—This bulletin reports the results of about 130,000 tests on the mechanical properties of woods, including data on both green and air-dry timber. A glossary of terms

used and a list of formulas used in computing are also given, together with a list of publications and papers dealing with the mechanical properties of timber.

The seasoning of wood, H. S. Betts (U. S. Dept. Agr. Bul. 552 (1917), pp. 28, pls. 8, figs. 18).—This bulletin enumerates the injuries to wood in seasoning, as checking, casehardening, honey-combing, warping, and collapse, and describes the processes of air seasoning and kiln-drying. Tabular and graphic data are given on the average weights and shrinkages of various species of wood and the rate at which crossties, poles, and sawed timbers of several species lose moisture when freely exposed to the atmosphere.

Creosoting for estate purposes, W. P. GEEENFIELD (Quart. Jour. Forestry, 11 (1917), No. 2, pp. 94-111).—The use of creosote as a preservative for farm and estate structural timber is discussed.

[Farm machinery directory] (Farm Machinery, No. 1342 (1917), pp. 20-24).—This directory lists the specifications for 188 internal-combustion tractors, 129 plows for tractor use, 23 huskers and shredders, and 104 silo fillers.

Public tests of motor cultivation at Avignon, E. Zacharewicz (Prog. Agr. et Vit. (Ed. l'Est-Cenire), 37 (1916), No. 31, pp. 109-115).—Tests of six tractors on breaking and deep plowing of loose alluvial soil are reported. The soil was dry and rather tenacious. The following table gives the results on breaking:

Horsepower.	Depth of plowing. Width of plowing.		Area plowed.	Duration of test.		Fuel con- sumption.	
	Cm.	Meters.	Sq. meters.	Hr.	Min.	Liters.	
12-20	11	1.00	9, 630	2	54	26, 00	
12-24	10	1.15	9,423	2	49	21.59	
8-16	10	.90	9,210	3	5	22, 30	
8-16	12	1.15	9,170	2	6	15, 12	

Tests on soil breaking.

The following table gives the results on deep plowing:

10-20 12-25

Horsepower.	Depth of plowing.	Width of plowing.	Area plowed.	Duration of test.		Fuel con- sumpti n.	
	Cm.	Meters.	Sq. meters.	Hr.		Liters.	
12-20	20	1.00	9,519	3	26	30.0	
12-24	20	1. 15	9, 525	0	0	30.0	
8-16	20	. 90	9,24)	4	3	35.0	
8-16	20	. 65	11, 220	4	0	31.9	
10-20	20	. 70	9, (c)()	4	12	26, 4	
12-25	21	1. 15	10,400	3	47	30. 5	

Tests on deep plowing.

Tractor specifications, 1917 (N. G. E. A. Bul., 2 (1917), No. 16, pp. 24; abs. in Gas Engine, 19 (1917), No. 6, p. 278).—Detailed specifications for 95 different tractors are given.

Note on fencing construction, T. Gilbert (Dept. Agr. Bombay Bul. 81 (1916), pp. 3, pls. 8).—This bulletin describes briefly a few practical points to be observed when creeting wire fences with wooden posts, with special reference to conditions in India.

Dairy and general-purpose barns, F. M. White (Nat. Lumber Mantrs. Assoc., Trade Ext. Dept. Farm Bul. 7 (1917), pp. 40, figs. 31).—This bulletin deals with site and location, general shapes, light, ventilation, stalls, floors, and feed alleys

of dairy and general-purpose barns and gives details of construction. Diagrammatic illustrations of six types of barns are included.

Barns for work animals, B. Youngblood (Texas Sta. Bul. 210 (1917), pp. 3-28, figs. 18).—It is stated that "satisfactory barns, large enough only for the work stock and a year's supply of feeding stuff, can be constructed in Texas at a cost of from \$25 to \$50 per animal. If as much as from \$100 to \$300 per animal is put into the barn, a proportionate amount of extra storage space for additional hay, grain, seeds, and so forth, may be had at less additional cost than would be the case if a separate storage building were constructed."

Suggestive plans are given which demonstrate principles applicable to Texas conditions. These are to be modified to meet local conditions. "The plans given begin with the cheapest possible, and end with a moderate-priced structure. The chief difference is in the size, convenience in feeding, and the amount of extra storage space supplied. No general-purpose barn plans are given, for the reason that it is better under southern conditions to have special-purpose buildings, separate and apart."

Bills of material and lumber necessary for the construction of various sized barns for work animals are also included.

Measuring silage and capacity of silos, L. W. Chase (Nebraska Sta. Circ. 1 (1917), pp. 14, figs. 5).—As the result of silage weighing experiments a new table of weights of silage is proposed for determining the capacities of silos, the rule for which assumes that silage settles 10 per cent after filling ceases. A comparison of the new weights with those established by King at the Wisconsin Station shows that the new weights are from 11.5 to 13 per cent less than the Wisconsin weights. The new table of weights was found to be very nearly correct on the basis of actual weighing, being if anything a fraction too large.

The proposed weights are given in the following table:

Depth of silage.	Weight per cubic foot.						
Feet.	Lbs.	Feet.	Lbs.	Feet.	Lòs.	Feet.	Ibs.
1	16. 13	14	25. 24	27	32.91	39	38.48
2	16. 89	15	25. 88	28	33. 43	40	38.88
8	17.64	16 17	26. 52	29 30	33.94	41	39. 27
4	18.38		27. 15	30	34. 44	42	39.65
5	19. 12	18	27. 77	31	34.93	43	40.02
6	19.83	19	28.38	32	35. 41	44	40.39
7	20.54	20	28.99	33	35. 88	45	40.75
8	21. 24	21	29. 58	34 35	36.34	46	41.11
9	21.93	22	30. 16	35	36. 79	47	41.46
10	22.61	23	30.73	36	37. 23	48	41.81
11	23. 28	24	31. 29	37	37. 65	49	42. 16
12	23.94	25	31.84	38	38. 07	50	42.50
12 13	24. 59	26	32.38				

Weight of silage per cubic foot.

Tables are also given showing the relative capacities of silos and estimated tonnage of silage by volume, together with information regarding the determination of silo capacities. The experimental results on which the tables are based are included.

Poultry houses and poultry equipment for Texas, R. N. Harvey, J. C. Olsen, F. W. Kazmeier, and T. J. Conway (*Texas Sta. Bul. 207 (1917)*, pp. 23, flgs. 17).—Plans of poultry houses and equipment are given and discussed, which, it is stated, with modifications of structure to fulfill needs imposed by climatic conditions may be used satisfactorily in almost any locality.

#### RURAL ECONOMICS.

The farmers' handbook, compiled by P. G. GILDER (Sydney, N. S. Wales: Dept. Agr., 1916, 2. ed., pp. VI+886, pls. 5, figs. 443).—This handbook is written for the use of practical farmers as well as a textbook for agricultural colleges, and high schools in New South Wales, and covers the entire field of agriculture with the exception of live stock, which subject is to be treated in a separate volume. The text is profusely illustrated.

The Federal Office of Markets and Rural Organization, J. C. GILBERT (Agr. of Mass., 1916, pp. 109-121).—The author describes the various activities of the Office of Markets and Rural Organization of the U. S. Department of Agriculture, as well as the marketing activities carried on through State bureaus and colleges of agriculture.

Functions of a State bureau of markets, A. E. CANCE (Agr. of Mass., 1916, pp. 122-134).—The author discusses the field to be covered by the State bureau, as well as the State agricultural colleges, and calls attention to conditions in the various States.

Cooperative purchasing and marketing organizations among farmers in the United States, O. B. Jesness and W. H. Kerr (U. S. Dept. Agr. Bul. 547 (1917), pp. 82, pls. 15).—The authors discuss the early history and growth of cooperative organization, different types of organizations and their characteristics, cooperation in representative States, representative types of cooperative organizations, and agencies which assist farmers in organizing. Statistical data are given showing the number of farm organizations, volume of business, and membership. There is also a brief digest of State cooperative laws and the text of a portion of the Clayton Amendment to the United States antitrust laws. A selected list of publications on cooperative purchasing and marketing is appended.

The county farm bureau, B. H. CROCHEBON (California Sta. Circ. 166 (1917), pp. 16, figs. 12).—The author points out the functions of the farm bureau, general plans of organization, methods of handling demonstrations, etc. He also includes a model constitution and by-laws.

List of county and local agricultural societies, L. H. Wible (*Penn. Dept. Agr. Bul. 296 (1917)*, pp. 9).—This bulletin contains a list of local agricultural and horticultural societies, with dates of fairs to be held in Pennsylvania in 1917, information regarding attendance in 1916, receipts, premiums, etc.

Cooperative credit for the United States, H. W. Wolff (New York: Sturgis & Walton Co., 1917, pp. V+349).—The author has endeavored to describe the cooperative credit organizations existing in the various European countries, with reference to their adaptability to conditions in the United States.

A survey of insurance of damage by fire to crops and forests, E. Vidière (Précis D'expertises Aprés Incendies des Récoltes et des Bois. Paris: Libr. Agr. Maison Rustique, [1916], pp. VII+484, pl. 5, figs. 18).—This report discusses, for France, the extent of the damage and methods of measuring the loss or destruction by fire of various types of crops, live stock, and forests.

The Torrens system of land title registration, F. B. Bomberger (Md. Agr. Col. Bul., 14 (1917), No. 2, pp. 8).—This contains a brief review of the history of the Torrens system and of its principal provisions.

[Italian rules governing agriculture], D. F. WILBER (U. S. Dept. Com., Com., Rpts., No. 181 (1917), pp. 460-463).—These pages contain parts of the decrees relating to agrarian contracts, the general use of agricultural machines, and the selection of agricultural committees and arbitrating committees for judicial districts.

Rural index, H. L. Hollister (Chicago: Author, 1917 ed., pp. [23], pl. 1, figs. 3).—This volume outlines a system for numbering rural homes so that they may be located as readily as city homes are by their street number.

Pounds to bushels tables, E. D. Davis (Minneapolis, Minn.: Author, 1916, pp. 40).—Tables are given for reducing pounds to bushels for oats, barley, buckwheat, shelled corn, ear corn, rye, flax seed, wheat, peas, beans, clover seed, and potatoes. Instructions are also given for determining the value of a load of grain, measuring the contents of bins, etc., measuring ear corn in a crib, measuring coal in a shed, computing freight rates per bushel from freight rates per hundred, estimating the value of mixed feeds, and loading cars by measurement.

Marketing grain at country points, G. Livingston and K. B. Seeds (U. S. Dept. Agr. Bul. 558 (1917), pp. 44, figs. 4).—Among the conclusions brought out by the authors are the following:

"Price and other factors being equal, farmers should patronize houses remaining open throughout the entire year.

"The producer of high-quality grain often receives less than it is worth in order that an equal price may be paid to a grower of grain of inferior quality. The farmer who delivers clean, dry, sound grain should receive a premium over the price paid to his more careless competitor. Farmers who deliver grain of inferior quality should be willing to submit to a discount. . . . It is likely that the standardization of grain produced in a community would not only result in a reputation for uniform quality which at times may command a premium over general market prices, but also reduce the cost of handling grain through the local elevator.

"While the 'scoop-shoveler' is usually a disturbing element, often causing loss to farmers and others having business relations with him, it is undoubtedly true that he frequently acts as a restraining influence upon the country dealer.

"Contracts with farmers for future delivery of grain should be entered into only after the interests of both parties concerned are safeguarded by a written contract clearly and concisely setting forth all the details of agreement. . . .

"When many elevators serve a community bad practices are usually introduced into the business, which increase the cost of marketing the farmer's grain and depreciate the value of all houses in the town and surrounding territory. Cooperative associations, as well as independent dealers, who desire to enter the business should purchase existing plants if this is practicable rather than build new ones.

"Losses from shrinkage and overgrading are usually ignored by country elevators. Managers should maintain a system of bookkeeping which shows accurately these as well as all other expenses, and a study of the results obtained should enable them to conduct their business in an economic and profitable manner. . . .

"When the organization of a cooperative-elevator association is contemplated, careful consideration should be given to the needs of the community for additional marketing facilities. Usually it is unwise to place too much confidence in the statements made by outsiders regarding the profits to be derived and the cost of operating a country elevator. Farmers should investigate fully the business circumstances which are to surround the new enterprise before affiliating themselves with the proposed cooperative-elevator association."

Farm labor [conditions in Canada] (Agr. Gaz. Canada, 4 (1917), No. 5, pp. 387-393).—These pages contain a series of articles indicating the plans adopted in a number of Provinces for the purpose of securing farm help necessary at the various seasons of production.

Labor conditions among the forest workers in Sweden, G. Huss (Sveriges Off. Statis., K. Soc. Styr., 1916, pp. 399, figs. 66).—This is a review of the social and labor conditions, wages, and hours of lumbermen and others employed in the forests of the Värmland, Dalarna, and Norrland regions of Sweden.

Notes on methods and costs, California crop production, R. L. Adams (Berkeley, Cal.: Univ. Cal., [1917], pp. [7]+140).—This volume contains data showing the requirements and methods of growing and cost of production of the various crops in that State. The statements are based upon the present practice of commercial producers, and are not designed to indicate what should be done but rather what is being done by men specializing in these crops. It also contains data concerning work capacity of farm machines, rules for determining work of implements, a day's work per man, a day's work per crew, annual amount of work required to care for live stock, costs of building materials, costs of fencing, costs of farm implements, costs of miscellaneous equipment, and annual rate of depreciation of farm machinery.

Meeting the food crisis, A. M. Soule (Atlanta, Ga.: South. Bell Telephone & Telegraph Co., 1917, pp. 19).—In this speech the author discusses the deficit in food crop in Georgia, and the increase necessary to enable the State to feed itself. He also points out methods that may be used to obtain the necessary increase.

The food supply in New England, E. F. McSweener (Boston, Mass.: New England Federation for Rural Prog., 1917, pp. 14).—The author discusses the changes in the system of farming in New England, its effect upon the food supply, and some methods that may be adopted to improve it.

The food supply of the United Kingdom (London: Bd. Trade, 1917, pp. 35).—This report, drawn up by a committee of the Royal Society of London, discusses the food supply in the period of 1909–1913, the proportion of home produce and imported products used, the quantities of various classes of food used during 1916, the ration for the civil and military population, and possible methods of economizing the available food supply. The suggestions given include a better recovery of flour in milling, increase of economy in meat production, increase in the protein available for human consumption by increasing the manufacture of cheese at the expense of butter making, use as food of materials at present employed in brewing and distilling, and the diverting of food now used as feed for stock to use for human food.

Production of food in Scotland, E. Wason et al. (Scot. Dept. Com. on Food Prod. Rpt., 2 (1916), pp. 6).—This report discusses the land available for increased food production, methods of increasing labor supply, manures, and implements.

[Increasing agricultural production in France], H. HITIER (Bul. Soc. Encour. Indus. Nat. [Paris], 116 (1917), I, No. 3, pp. 582-594).—This article outlines the extent of the agricultural production in France, compares it with conditions in other countries, suggests methods of making agriculture more intensive, and gives recommendations adopted by the National Association of Economic Expansion with reference to the expansion of production.

The wheat question, Perchot (Vie Agr. et Rurale, 7 (1917), No. 25, pp. 433-440).—The author points out the available home supply of wheat and the possibilities of increasing it, the influence of Government intervention through price fixing and the guaranteeing of price, and the influence of price on production.

Food crisis in Portugal (Bol. Assoc. Cent. Agr. Portuguesa, 19 (1917), No. 7, pp. 217-224).—These pages outline methods that may be used to increase the production of cereals, sugar, cotton and other fibers, oil seeds, horticultural products, and live stock.

[Agricultural development in Navarra], D. NAGORE Y NAGORE (Servicio de Agricultura y Ganadería. Pamplona, Spain: Prov. Printer, 1917, pp. 43).—In this report are discussed the various types of agricultural organizations found, types of agricultural machines used and difficulties encountered in introducing new machines, natural products in Navarra, agricultural practices in different communities, and kinds of live stock and extent of live stock production.

Some observation on agricultural work in Egypt, Britain, America, and Japan, W. Roberts (Lahore, India: Govt., 1917, pp. 12+XVIII).—This report deals with the methods of growing cotton in the countries named, and schools and educational methods used for teaching the best practices.

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt.. 3 (1917), No. 8, pp. 69-80, fig. 1).—This number contains the usual data relating to crop conditions, estimated farm value, average prices received by producers, and range of prices of agricultural products at important markets. It also includes special reports on the monthly marketings of wheat by farmers, production of sugar in the Philippine Islands, the acreage of beans by varieties, acreage of corn, peas, tomatoes, and snap beans contracted for by canners, and crop conditions in Florida and California, as well as on silos in the United States, fertiizers used on cotton, index numbers of food supplies in various countries, manufacture of vegetable oils for edible purposes, percentage and index number of foodstuffs in the export and import trade of the United States, data showing when farmers sell their crops, etc.

[Agricultural statistics of Indiana] (Bien. Rpt. Bur. Statis. Ind., 16 (1915–16), pp. 444-446, 543-547, and 564-662).—These pages contain data relating to the rural population, the increase of farm land, the assessed value of farm land, climatology, crops, and live stock. These data are based upon reports obtained by the township assessors.

Agricultural statistics for Wisconsin, 1915 and 1916 (Wis. Dept. Agr. Bul. 11 (1917), pp. 145-192).—This report contains statistical data, showing for 1916, by counties, the acreage, production, yield per acre, and area of the principal crops; number and value of live stock; number of silos; and average farm prices of important farm products on December 1, 1916.

Annual statistical report of the New York Produce Exchange for the year 1916 (Ann. Statis. Rpt. N. Y. Produce Ex., 1916, pp. 139).—This volume contains data relating to the receipts and exports of agricultural products from New York City, together with daily prices, freight rates, and the production of crops of the United States and in foreign countries for 1916, with comparative data for earlier years.

[Agriculture in Norway] (Statis. Aarbok Konger. Norge, 36 (1916), pp. 24-35).—These pages supplement data previously noted (E. S. R., 37, p. 93), by additional statistics for the year 1916.

Returns of produce of crops in Scotland (Agr. Statis. Scotland, 4 (1915), pt. 2, pp. 59-79).—These pages continue data previously noted (E. S. R., 33, p. 894) by adding statistics for a later year.

[Agricultural statistics of British India for the year 1915–16], G. F. Shirras (Agr. Statis. Brit. India, 1915–16, pp. 11).—This report contains data by Provinces, showing the area cultivated and uncultivated in 1916 with comparative data for earlier years, area under irrigation, area under different crops, number of live stock, plows and carts, number of transfers of property and area transferred, together with area assessed, and incidents of land revenue settlement.

Live stock statistics (Internat. Inst. Agr. Rome, Internat. Crop Rpt. and Agr. Statis., 8 (1917), No. 5, pp. 390-392).—Data are shown indicating the num-

ber of the various classes of live stock in France on December 31, 1916, July 1, 1916, November 1, 1915, and December 1, 1915, together with similar data for Cuba for the second half year of 1915 and of 1916.

#### AGRICULTURAL EDUCATION.

Agricultural education and research (Rpt. Bd. Agr. Scot., 5 (1916), pp. XII-XVIII).—An account is given of the progress made in 1916 in the agricultural education and research work under the control of the Board of Agriculture of Scotland.

Annual report of the director of the elementary agricultural education division, New Brunswick, 1916, R. P. Steeves (Dept. Agr. New Brunswick, Ann. Rpt. Dir. Elem. Agr. Ed. Div., 1916, pp. 26, pls. 2, figs. 2).—This is a rereport on the progress made during the year in instruction in nature study and elementary agriculture, and the training of teachers in these subjects, including some of the difficulties encountered in the work.

During the year, 78 schools received grants for instruction in nature study and elementary agriculture with school gardening, an increase of 23 over the previous year. The number of school children receiving regular instruction in these subjects increased over 1,000, and the number of home plats, varying from 4 acre to a few square feet each, from 378 to 727. The publication of a rural education monthly for the schools was begun to call attention to rural problems, to deepen interest in country life, etc.

[Agricultural instruction in Ontario, 1916], W. H. Hearst (Rpt. Min. Agr. Ontario, 1916, pp. 5-20, 28-34, 46-77, figs. 25).—This report contains information for 1916 similar to that given for 1914 (E. S. R., 34, p. 597). The number of school fairs held increased from 234 in 1915 to 275 in 1916, the number of children taking part from 48,386 to 60,262, and the number of home plats from 51,243 to 55,947. Among new features introduced in this work are interschool live-stock judging competitions and weed naming and driving contests. Public speaking contests are now recognized as an important feature of a school fair.

Ultuna agricultural institute and farm, 1916 (Upsala, Sweden: Ultuna Landtbr. Inst., 1916, pp. 32, pl. 1, figs. 12).—A report on the history, development, and present organization of the instruction and experimental work of this institution.

Agricultural education in Bulgaria, D. I. MURPHY (U. S. Dept. Com., Com. Rpts., No. 110 (1917), pp. 554, 555).—A brief statement is given concerning the course of study, cost, and entrance requirements of the agricultural schools at Roustchouk, Sadovo, Pleven, and Orhanie, the latter for girls, and of eight agricultural schools of lower grade.

[Rural education] (Education, 37 (1917), No. 9, pp. 541-589).—The principal addresses given at the Fifth Annual Conference on Rural Education held at Worcester, Mass., in March, 1917, are presented as follows: The New Conception of the Rural School Problem, by William B. Aspinwall; A Rational Program for Rural Education, by Payson Smith; How the Curriculum May Better Meet Present Day Social Needs, by William D. Hurd; Vitalizing School Studies—the Situation in One Massachusetts Town, by Mrs. Ella M. Clark; Vitalizing a Rural School Course, by Allen S. Woodward; The Revitalized Course of Study, by J. C. Muerman; Vitalizing Rural School Work in Massachusetts, by Grace C. Smith; An Example of a "Vitalized" School, by M. Harriet Bishop; and First Aid to the Citizen Makers, by Joseph D. Eggleston.

The school inspector and rural science, E. ROBINSON ET AL. (Agr. Gaz. Canada, 4 (1917), Nos. 6, pp. 499-507; 7, pp. 608-610).—This is a series of brief

articles by school inspectors in Nova Scotia, Ontario, and Saskatchewan on what the school inspector can do to promote rural science instruction in the schools.

The agricultural subjects, W. A. Broyles (Quart. Jour. Univ. N. Dak., 6 (1916), No. 2, pp. 138-144).—The author discusses the wide range of the field of agricultural subjects, their cultural value, and elements of live educative processes in and out of school.

"Snap courses" in college: Agriculture v. engineering, F. H. Blodgett (School and Soc., 6 (1917), No. 135, pp. 91-96).—The author presents an analysis of the two fields of agriculture and engineering in an effort to discover why the biological sciences are so often regarded as "snap courses" in the average college. In his opinion, "It seems probable that the disrespect so often felt by students, either for the courses in the biological sciences themselves, or for the students who select such courses, will be largely diminished if there can be developed a more definite goal toward which the whole body of teaching and experiment may converge, each step being coordinated with each other step, and each essential to the whole. It should be the aim of agricultural science (or of biological science, of which agriculture is the field of application), to discover the sequence of details which together are necessary to build a foundation for the growth of the subject for its development into a branch of knowledge coordinate with the older topics."

Outline of experiments for departments of agriculture in the public schools of Louisiana, P. L. Guilbeau and T. H. Harris (Baton Rouge, La.: Dept. Ed., pp. 43, fig. 1).—The author outlines exercises and experiments in agriculture to be used in connection with the various texts studied in grades 8, 9, and 11 of the public schools of Louisiana.

Dairy education, R. A. Pearson (Lincoln, Nebr.: Univ. Nebr., 1917, pp. 12).—In this address, delivered at the dedication of Dairy Industry Hall at the University of Nebraska on January 17, 1917, the author discusses the growth of the dairy industry, the development of dairy cattle, improvements in methods of dairying, the recognition by the American people of the importance of making ample provision for instruction in the fundamental and vital industries of this country, the dignity of agricultural education, and future problems in dairying.

The present position and future developments of dairy education.—Science, J. Mackintosh (Jour. Brit. Dairy Farmers' Assoc., 31 (1917), pp. 92-107, fig. 1).—The author gives a concise account of the system of dairy education which has been developed in Great Britain. This comprises instruction (1) provided by counties in the form of itinerant instruction and instruction at a fixed institution, either a county farm school or an agricultural college, or both, and (2) at provincial institutions. The most necessary lines of future development are also indicated.

The present position and future developments of dairy education.—Practice, P. McConnell (Jour. Brit. Dairy Farmers' Assoc., 31 (1917), pp. 85-91).—This is a review of progress made in practical dairy instruction in Great Britain, with special reference to feeding, records, selection, sanitation, and inspection. In the author's opinion "the best equipped dairy farmer—apart from questions of capital—is one who has spent some time in his youth on a dairy farm, taking his share of the work . . . and who then, equipped with practical knowledge, attends the usual courses at a dairy school."

The part which women might play, Margaret Shanks (Jour. Brit. Dairy Farmers' Assoc., 31 (1917), pp. 108-118).—This is a review of what women have done in dairy production in the past and the lines upon which they have been advancing in recent years, and a consideration of what additional or special

help they could give in the effort to increase the dairy production of Britain. The latter, the author concludes, "is a question first of education: Grades of education to suit the different classes of women who engage in dairying and, above all, an education that will come right into the farmhouse and influence the minds of the wives and daughters there. . . . And, added to that, let them have equal and honorable place beside men in all associations that concern the welfare of the industry in which they both labor with head and hands."

Productive dairying, R. M. Washburn (Philadelphia and London: J. B. Lippincott Co., 1917, pp. XII+432, pls. 2, figs. 129).—The object of this book is to furnish a foundation and guide for good practice in dairying. It is written for use in high schools, schools and colleges of agriculture, general courses, rural consolidated schools, and farmers. Its seven parts deal respectively with the why of dairying, the dairy breeds, care and management of dairy cows, winter feeding, clean milk production, farm dairying, and market milk. Tables showing the composition of feeding stuffs and data as to fat estimation are appended.

A first-year course in home economics for southern agricultural schools, Louise Stanley (U. S. Dept. Agr. Bul. 540 (1917), pp. 58, figs. 2).—This bulletin outlines a first-year course in home economics, consisting of 160 lessons in cooking and sewing with related hygiene and sanitation, for southern agricultural schools. It emphasizes the connection between such instruction and actual home experience, discusses methods of teaching, and offers suggestions for correlating the work with other school subjects. A list of publications of this Department of interest in connection with this bulletin is appended.

The story of foods, F. Crissey (New York and Chicago: Rand McNally & Co., 1917, pp. 501, figs. 271).—This book gives a comprehensive world view of foods and their geographical and industrial background. It deals especially with the human agencies concerned in the production, preparation, and distribution of foods, including the work of the wholesaler and retailer. The foods dealt with are the grains, fruits, vegetables, dairy products, honey, poultry, meat, fish, canned and condensed foods, dried fruits, coffee, tea, and other drinks, nuts, sugar, spices, salt, and table delicacies.

Elements of the theory and practice of cookery, Mary E. Williams and Katharine R. Fisher (New York: The Macmillan Co., 1916, 2. ed., rev. and enl., pp. XIII+405, pls. 16, flgs. 30).—This is the second edition, revised and enlarged, of a text in domestic science which may be used for individual or group instruction, and the subject matter of which can be covered in four terms or two school years by pupils in the sixth and seventh, or seventh and eighth grades of school, one two-hour lesson being given each week. The book deals with the following topics, taken up in an order that experience has shown to be natural and convenient: Homes and home-making; some starchy plants; tissue-building foods; bread; food in its relation to life; meat, fish, and poultry; fuel foods; fruits and vegetables; sugar and sweets; the preservation of food; special diets; tea, coffee, cocoa; the serving of food; laundering; and digestion. Principles are taught in connection with their application, followed by a classification of foods, their chief constituents, economic and food values, etc. Bibliographies are added.

Wool: The raw materials of the woolen and worsted industries, S. H. Habt, edited by E. W. France (Philadelphia: The Philadelphia Textile School, 1917, pp. XX+228, pl. 1, figs. 91).—This book has been prepared for use as a text in connection with the course in the raw materials of the wool industries at The Philadelphia Textile School. It makes an effort to follow the various raw materials of the woolen and worsted industry from their origin to the point where

actual machine processing begins, and comprises the following chapters: Structure, properties, and characteristics of wool; classes of fleece wool, including brief descriptions of important long and medium-wool breeds of sheep; grading and sorting; shrinkage; shearing, preparing, and marketing wool; pulled wools; mohair and other textile hair fibers; wool substitutes and waste products; fabric requirements; and historical synopsis. Statistics of wool production and importation in the United States, distribution of sheep, score cards for sheep, and other useful data are appended.

[Conference of the Alabama Home Economics Association] (Ala. Girls Tech. Inst. Bul., n. ser., No. 38 (1916), pp. 37).—This bulletin contains the following addresses given at the second annual conference of the Alabama Home Economics Association held at the Alabama Girls' Technical Institute, Montevallo, January 27–29, 1916: Home Economics in the New and Socialized Curriculum, by Z. Judd; Vocational Phases of Household Arts Education, and Survey of Household Economics in the High School, by Mary S. Woolman; and Club Work for Women and Girls; and a round table discussion of What Has Been Done in Home Economics in Alabama during 1915, including an outline of a suggested four-year course in home economics in the high schools of Alabama.

Report of the supervisor of women's institutes, Hazel E. Winter (Rpt. Agr. New Brunswick, 1916, pp. 51-55).—This is a report on the growth, patriotic work, short courses, and the fourth annual convention of the women's institutes of the Province of New Brunswick.

### MISCELLANEOUS.

Monthly Bulletin of the Ohio Agricultural Experiment Station (Mo. Bul. Ohio Sta., 2 (1917), Nos. 7, pp. 211-247, figs. 21; 8, pp. 249-281, figs. 14).—These numbers contain, in addition to several articles abstracted elsewhere in this issue and miscellaneous notes, the following:

No. 7.—Buckwheat Culture.—A Bread-making Grain Commanding Unusual Attention this Year, by C. G. Williams; Wheat-flour substitutes.—Rolled Oats, Corn Meal, and Buckwheat Flour Provide Cheaper Food, by Mabel K. Corbould; Diseases of Wheat.—Methods of Control Possible by Seed Treatment, by A. D. Selby; Grain-bin Sanitation.—Insect Injuries to Stored Cereals Prevented by Cleaning Bins, by W. H. Goodwin; Silage for Fattening Cattle.—Economy in Winter Feeding Results, Experiment Proves, by B. E. Carmichael; Thinning Fruit.—Greater Yields of High Quality Result from Removing Part of Crop, by W. J. Green; and Insect Pests of Vegetables.—Methods of Control Suggested for the More Troublesome Kinds, by J. S. Houser.

No. 8.—Harvesting Soy Beans.—Special Care Needed in Cutting and Curing the Crop, by C. G. Williams, an extract from Bulletin 312 (E. S. R., 37, p. 235); Late Blight of Potatoes.—Weather Conditions May Necessitate Continued, Thorough Spraying, by D. C. Babcock; and Fuel and the Woodlot.—Marketing Wood Provides Winter Labor and Improves Timber Areas, by E. Secrest.

Monthly bulletin of the Western Washington Substation (Washington Sta., West Wash. Sta., Mo. Bul., 5 (1917), No. 5, pp. 62-76, figs. 4).—This number contains brief articles on the following subjects: Use of Soiling Crops, by H. L. Blanchard; Eradication of Rootstock Weeds, by E. B. Stookey; A Commercial Poultry Plant, by G. R. Shoup; Agricultural Fair Exhibits; Mountain Beavers; and Farmers' Excursions,

# NOTES.

Connecticut College and Stations.—The legislature has authorized the trustees of the college to establish at least two scholarships from each county, and appropriated \$4,000 for the purpose for the period ending September 30, 1919. The legislature also provided for State aid to one corporation or association organized in each county for the purpose of providing instruction and practical demonstration in agriculture and home economics, promoting advanced business methods among farmers, or assisting in any manner in the development of agriculture and the improvement of country life. Each organization may obtain annually from the State an amount equal to the sum received by it otherwise than under the provisions of the Federal Agricultural Extension Act, but not less than \$1,000.

The chemical laboratory, occupied by the college and Storrs Station, was totally destroyed by fire, November 26, 1917. The apparatus and chemical laboratory of the station were destroyed, together with a large part of the samples of experimental crops which were awaiting analysis. The chemical work of the station is for the present being carried on at the State Station at New Haven.

John P. Street, chemist in charge of the analytical laboratory at the State station, has been granted leave of absence to become captain in the Sanitary Corps of the National Army. His duties are expected to deal largely with problems regarding the food supply at the cantonments. Waldo L. Adams, chemist, resigned December 1 to accept a commercial position.

Purdue University and Station.—A tract of 385 acres of virgin forest land in Randolph County has been given the university by the late Mrs. Henry Davis. Under the terms of the will the property is to be maintained as the Henry Davis Forestry Farm. The forest must be preserved and no commercial cuttings made, the tract used as a refuge for song birds, and experiments undertaken for the acclimatization of useful plants.

H. J. Reed, associate horticulturist, has been appointed assistant to the director. George N. Hoffer, assistant professor of botany in the school of science, has been transferred to the station as associate in botany, his college work being assumed by Eben H. Toole of the Kansas College. R. B. Easson, assistant in the poultry extension department, has resigned to enter a reserve officers' training camp, and H. C. Mills, associate in dairy manufactures. has resigned to engage in commercial work.

Kentucky University and Station.—Thomas P. Cooper, director of station and extension work in North Dakota, has been appointed dean of the college of agriculture and director of the station beginning January 1, 1918. R. H. Wilkins and L. B. Mann, of the animal husbandry department, have resigned. Recent appointments include J. R. Humphrey of the U. S. Department of Agriculture as head of the department of markets, and J. H. Martin, T. G. Yaxis, and H. C. Rhodes as assistants in animal husbandry.

Minnesota University and Station.—Dr. E. Dana Durand has resigned as chief of the division of research in agricultural economics to devote his entire attention to work in the college of science, literature, and arts. George B.

Holm, research assistant in agricultural biochemistry, has been commissioned first lieutenant in the Sanitary Corps of the Army Medical Department, and is expected to be assigned to investigations in the Gas Defense Service. G. R. McDole, assistant in soils, has enlisted in the Sanitary Corps for duty in the Gas and Flame Service.

F. L. Washburn has been transferred from professor of entomology in the college of agriculture, entomologist in the station, and State entomologist, to become professor of economic vertebrate zoolgy beginning February 6. Dr. C. C. Palmer, professor of physiology in the division of veterinary medicine, has accepted an appointment as professor of bacteriology, physiology, and hygiene at the Delaware College. Shinjiro Sato, assistant in agricultural biochemistry, has resigned to return to Japan.

Recent appointments include G. E. Weaver as assistant professor of dairy husbandry and assistant dairy husbandman, H. R. Searles as instructor in dairy production, and Paul L. Miller as superintendent of the Morris school of agriculture and substation, vice E. C. Higbie resigned.

Missouri University and Station .- M. F. Miller has been appointed assistant dean and director beginning November 1, 1917. Other appointments include Dr. O. S. Crisler as superintendent of the serum production work in the department of veterinary science, W. L. Nelson as assistant in the agricultural extension service, Frank L. Wright as assistant in boys' and girls' club work, L. L. Alexander as instructor in farm crops, Dr. C. H. Hays as extension assistant professor of veterinary science in charge of hog cholera extension work, Bliss F. Dana, M. H. Fohrman, and Turner H. Hopper as assistants in horticulture, dairy husbandry, and agricultural chemistry, respectively, Clifton R. Thomson, S. R. Miles, and I. F. Nuckols as assistants in animal husbandry, and E. H. Hughes as assistant to the dean and director and superintendent of short courses. R. R. Hudelson, assistant professor of soils, has been commissioned first lieutenant in artillery, E. M. McDonald, assistant professor in farm crops, as second lieutenant in infantry, and O. R. Johnson, professor of farm management, and F. C. Fenton, extension assistant in agricultural engineering, as second lieutenants in artillery. V. F. Payne, instructor in agricultural chemistry, resigned October 5.

Nebraska University and Station.—The corner stone of the new agricultural engineering building has been laid and it is expected that the building will be ready for occupancy next fall. Reinforced concrete construction has been substituted for steel in the new plans. Plans are also being drawn for a veterinary building, which it is hoped to erect in the spring.

H. B. Pier, assistant professor in animal husbandry, has resigned. H. W. Thurston, jr., has been appointed associate professor of plant pathology, vice G. K. K. Link on leave of absence from November 1, 1917, to take up special work with the U. S. Department of Agriculture. F. E. Mussehl, of the Wisconsin University and Station, has been appointed professor of poultry husbandry, vice M. E. Dickson resigned, effective October 20. R. P. Crawford has succeeded Floyd Wambeam, resigned, as agricultural editor. William B. Nevens, assistant dairy husbandman of the Illinois Station, has been appointed assistant professor of dairy husbandry. Miss Alice Loomis and Mrs. Emma R. Davisson have been granted leave of absence for the academic year, the former to take up work with the U. S. Bureau of Education and the latter to engage in extension work for the States Relations Service.

Nevada Station.—James B. McNair has resigned as assistant chemist, effective January 1, 1918. J. B. Menardi, assistant agronomist, has enlisted in the U. S. Navy.

Cornel! University.—The college of agriculture has been assigned by the State Vocational E lucation Board the task of training teachers of agriculture and directors and supervisors of agricultural subjects. The training of teachers of home economics is to be divided between the college, the State Teachers' College at Albany, and the State Normal School at Buffalo. It is expected that eventually about \$75,000 of the Federal funds will be available to the college annually, and that considerable graduate work will be developed by the department of rural education.

D. B. Carrick has resigned as instructor in pomology to accept a position in the Bureau of Markets of the U. S. Department of Agriculture.

Oregon College and Station.—A pruning school was held at the college the second week in December, with lectures and demonstrations in the forenoons of each week and pruning work in the nearby orchards in the afternoons. Some work on spraying was also carried on.

A joint antismut campaign has been conducted by the departments of botany, plant pathology, and farm crops, in cooperation with the U. S. Department of Agriculture as part of the plan to increase food production.

Ava B. Milam, head of the domestic science department, has been appointed dean of the school of home economics. Ralph McBurney, instructor in bacteriology, has been commissioned first lieutenant in the Sanitary Corps of the Army Medical Department. Chas. S. Brewster, of the Purdue University and Station, has been appointed instructor in poultry husbandry, vice A. C. McCulloch, now engaged in extension work in New Brunswick.

Other appointments include V. D. Chappell, instructor of dairy manufactures at the Iowa College, as assistant in dairy manufactures; L. W. Wing, as instructor in dairying; D. K. Tressler, of the Bureau of Soils of the U. S. Department of Agriculture, and E. H. Dougherty as instructors in agricultural chemistry; Bernard F. Sheehan as instructor in farm crops; L. F. Lingle as assistant professor and assistant in horticultural products; H. C. Woodham as instructor in horticulture; and E. J. Fjeldsted as instructor and assistant in animal husbandry, vice G. R. Samson.

Pennsylvania College and Station.—Plans have been approved for a commercial truck garden of about 10 acres. The work is to be done by students and is intended to afford an insight into commercial truck operations.

R. A. Andree, assistant professor in agronomy in charge of farm economics, has resigned to become head of the department of agricultural engineering at the Texas College. C. M. Arthur has resigned as instructor in agricultural extension to take up work connected with problems of distribution and marketing of farm products carried on with the Pennsylvania Committee on Public Safety. Dr. H. L. Fulmer, assistant professor of bacteriology, is now in military service. L. P. McCann, instructor in animal husbandry, resigned January 1, 1918.

Dr. D. S. Fox, assistant in farm management at the Montana Station, has been appointed assistant professor of farm management. Other appointments include E. L. Nixon as extension plant pathologist, C. A. Hunter as assistant professor of bacteriology and assistant bacteriologist, M. W. Lisse as assistant professor of agricultural chemistry, E. J. Klepper as assistant in botany, Chas. Cummings as instructor in dairy husbandry, and E. J. Holben as assistant in experimental agronomy.

Texas College and Station.—At the special session of the legislature, the acts establishing a West Texas Agricultural College and a Northeast Texas Junior A. and M. College were repealed. The John Tarleton Agricultural College at Stephenville and the Grubbs Vocational College at Arlington, junior colleges under the board of directors of the Texas A. and M. College, opened September

20. E. E. Binford, superintendent of the Beeville substation, became professor of agriculture in the John Tarleton College and was succeeded by I. E. Cowart, previously assistant professor of horticulture.

F. D. Fuller, formerly chief deputy State chemist of Indiana and more recently in commercial work, has been appointed chief of the division of feed control service. W. E. Jackson became assistant entomologist of the station, October 1, 1917, for work in combating foul brood. Dr. H. Schmidt, veterinarian, and Carl Abell, scientific assistant and station illustrator, are now in military service, the latter being succeeded by Miss Edith H. Phillips.

Virginia Truck Station.—A 75-acre farm in Accomac County has been rented for the use of the station in conducting experiments on sweet potatoes, Irish potatoes, strawberries, and other truck crops grown in the county. The farm will be equipped with modern buildings and operated for experimental purposes.

Albert White, instructor in horticulture at the Pennsylvania College, has been appointed assistant horticulturist, assuming his duties November 15.

Wyoming University and Station.—Dr. H. G. Knight, dean of the college of agriculture and director of the station, has accepted the corresponding position at the Oklahoma College and Station, effective February 1, and has been succeeded by A. D. Faville. Dr. H. M. Martin, assistant in animal diseases, is now in military service.

Society for the Promotion of Agricultural Science.—The thirty-eighth meeting of this society was held at Washington, D. C., November 12 and 13, 1917. The sessions were unusually well attended. The program dealt particularly with war conditions, but covered a wide range of subject matter.

The presidential address was given by Dr. Herbert Osborn at a joint session held with the American Society of Agronomy. Dr. Osborn took for his subject The Outlook in Agricultural Science, discussing some of the notable developments in various lines and some effects of the war upon agricultural science. He pointed out that when the war emergency arose, it found a great body of trained workers already mobilized, in whom the public had confidence and whose recommendations were accordingly widely followed. The outlook for material support of agricultural institutions he characterized as unusually favorable. The prospective shortage of younger workers he suggested might be lessened to some extent by the retention in service of older men who would ordinarily seek retirement. Since the immediate duty of agricultural science, as of all other interests, is to win the war, all efforts should be energetically put forth in this specific direction.

At the same session Dr. L. H. Bailey delivered an address of wide general interest entitled Permanent Agriculture and Democracy. This address was suggested by his observations of the agricultural situation in China, where 85 per cent of the people are engaged in agriculture but under a scale of living which he characterized as reduced to the lowest possible terms. On the basis of his observations he discussed such fundamental questions as the farmer's place in the Nation as the "keeper of the earth," the need of broad vision as well as specialized knowledge on the part of those attempting to advise on rural problems, the fallacy of too small holdings and overintensive methods, and the wide difference between "permanent" and "stationary" agriculture.

The program of technical papers was as follows: The Function of Organic Matter in the Maintenance of Soil Fertility, by C. E. Thorne; How Farmers Acquire Their Farms, by W. J. Spillman; Vegetation Experiments on the Availability of Treated Phosphates, by J. G. Lipman; Wheat Production and Consumption during Peace and War Times, by H. Snyder; Shall We Recommend

the Use of Magnesium Limestone? by A. G. McCall; A Revolution in the Methods and Theories of Soil Chemistry, by C. B. Lipman; Abortiveness As Related to Position in the Pod of the Ovules of the Legume, by B. D. Halsted; The Station's Part in Winning the War, by B. Youngblood; Have the Agricultural Colleges Met Their Obligations in the War Emergency? by W. D. Hurd; The Most Pressing Development Problem of American Agriculture, by C. V. Piper; Some Factors of Success and Failure in Dry Farming, by A. Kezer; Some Results Obtained in the Use of Sulphur As a Fertilizer, by A. B. Cordley; Promoting Practical Forestry Work, by F. W. Rane; Inosit Phosphoric Acid in Feeding Stuffs, by J. B. Rather; The Mineral Metabolism of the Milch Cow, by E. B. Forbes; Influence of Degree of Fatness on Utilization of Feed, by H. P. Armsby and J. A. Fries; and A Prospective New Forage Crop for the Irrigated Portion of the Northwest, by F. B. Linfield.

At the business session the secretary, Director C. P. Gillette, reported that a canvass of members as to the enrollment in the society of members of the American Society of Agronomy and the American Farm Management Association and the formulation of a joint program had resulted in an affirmative vote of 47 to 39. In accordance with the results of this canvass, the executive committee was instructed to work out details for such a plan of reorganization and report at the next annual meeting.

Dean R. W. Thatcher was chosen vice-president of the society, the remaining officers being reelected.

Miscellaneous.—The death is noted of Dr. Arthur T. Neale, director of the Delaware Station from its organization in 1888 until 1906 and in charge of agronomy and animal husbandry work until 1907. Dr. Neale was 65 years of age, a graduate of Wesleyan University and the University of Halle, and served as assistant chemist in the laboratories of both institutions. He was also chemist of the New Jersey State Station from 1880 to 1888.

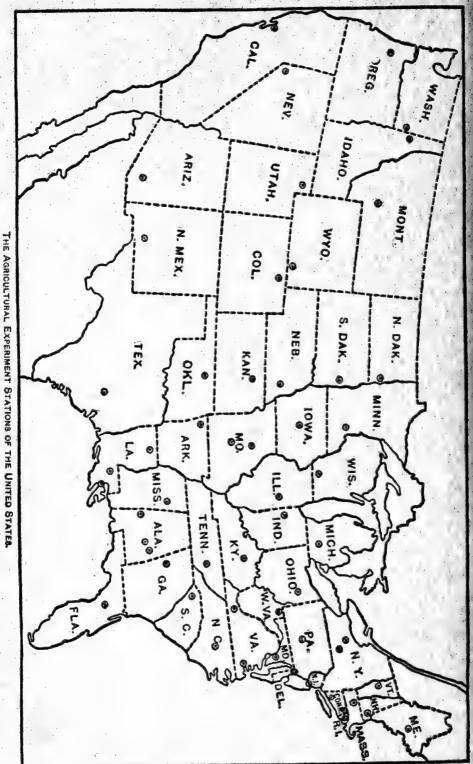

- Dr. C. H. Higgins, chief pathologist of animals branch of the Canadian Department of Agriculture since 1902, has resigned to engage in commercial work in New York City, and has been succeeded by Dr. S. Hadwen, previously in charge of the veterinary research laboratory of the department in British Columbia.
- T. B. Wood, professor of agriculture in the University of Cambridge, has been appointed to the Development Commission of Great Britain, vice A. D. Hall, now secretary of the Board of Agriculture and Fisheries.

The senate of the University of London has decided to institute for non-resident students a B. S. degree for courses dealing with the administration and management of urban and rural lands and estates.

- A. C. Monahan, specialist in agricultural education and rural school administration of the U. S. Bureau of Education, has been commissioned major in the Sanitary Corps of the National Army.
- W. V. Tower has resigned as director of the Porto Rico Insular Experiment Station at Rio Piedras.
